OK Actually, this looks good as long as you have a directional coupler for
the frequency of interest! Paul didn't say. (SWR Bridge, actual bridge,
for lower frequencies) You'll also have to allow for the difference in
location of the two samples by adjusting the line lengths to the two scope
probes intil they are both at the same "distance" from the load. Judging
phase shift from a circle can't be as good as simply looking at the two
waveforms. The scope horiz gain can be adjusted for some nice number of
divisions for each half cycle, say 9...
I've got a 100MHz. dual trace storage scope, but any directional
couplers around here only will be down to 130 Mhz at best... I do also have
a good bridge for down to 5 MHz., (also about 1 meter worth of stretch
line...so it is possible as long as the power level is within the bridge
capability.

Probably shouldn't admit this, but I always have to look it up, even though
I've designed them. Interestingly enough "Wilkenson" got some hits on
Google, so not every one checks...

P.S. You get to a point where your brain actually _fills up_ and nothing
else will fit until something falls out!... Yea, that's the ticket!

It is standard practice when you have a tight/rusty
screw but neither the tap nor the die for the thread
to drive a nut against the corrosion.

Stupid boy.

1615. Focus on Tek 2236 Scope

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-08-10 19:06:58 UTC
From: Rex <me@hutmail.invalid>
Message-ID: <ul6ih0psfai6aj6rrhomr5t8ge7a17nhi9@4ax.com>
Source record: 24097

I have a Tektronix 2236 Oscilloscope. I haven't used it in a while and when I did this week, I find the focus is very bad. It is barely usable with the focus control set fully ccw. With focus set in the center, the trace dot is about 1 graticle-square in dia.

The trace is plenty bright with intensity turned up, so I don't think the CRT is dying. With intensity turned way down and focus best (at knob limit) the traces are quite blurry.

I have the manual but haven't opened the case yet. I'm wondering if this is a common problem and if there is anything that I should look at first? Anyone have experience or informed suggestions?

Hello Paul, I have a similar type under testing but limited working
frequency range 1.8-60 Mhz at www.qsl.net/iw3hev. The performances are
not comparable to the VNA from N2PK but is good for antenna testing.

Indeed. In the case of most people in the populous at large, the
one-seventh of the brain that *is* used is concentrating on Fox TV.
This feeds the other 6/7 with the neurotransmitter, dopamine, which
tells them not to worry: everything's fine.

IIRC there are 5ea 1/2 watt 1meg or 510K (value depends on scope model) Ohm carbon resistors in there as a focus string that age and get flakey that very often causes this problem. They are in a row by the focus pot on the main board..... check those and replace if off value or open. I had a 2235 with the same problem once .... Jim Yanik, an ex Tek employee gave me this info and it fixed mine.

That said...BE CAREFUL in a scope..... HIGH VOLTAGE present.... 20,000 volts. Don't go inside unless you know what you are doing.

Mike, W9WIS

Steve,
A decent (not the dollar store variety) CATV splitter has directivity of
about 30 dB from 5Mhz to over 500 MHZ. I think this would do the job.

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday August 15th 2004
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20 for the first and
$15 for each additional at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,
will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and
W1XM/R-449.725/444.725 (PL 114.8/2A).

Sponsors: MIT Electronics Research Society
MIT UHF Repeater Association (W1XM)
MIT Radio Society (W1MX)
Harvard Wireless Club (W1AF)

I recommend for you a study scheme for the full Ham Radio
licence, because there is then a remote (because of your demonstrated
CBness below) chance that you will come across the gentlemanly
traditions of Ham Radio.

Stupid Boy.

Interesting - and answered in some of the less abusive postings
further down (thank you) - had the same experience, I bought a heap of
pre-made patch leads with PL259 plugs each end, but they wouldnt screw
down to all the so239 sockets in the workshop - didnt really think
about it, just put it down to lousy quality control (they were only $2
each) so binned them. Never knew there were two standards before.....

While the Eagle Layout software (that's where the above link points to)
has room for improvement in the 'easy to use/learn' department it is
powerful and reliable.
It also features a usable free version whose limitations don't prevent
its usage for small to medium projects. The free version allows for a
one-page schematic (any size), an 100x80mm board size and two layers.

All other packages I've tried are either too limited, too buggy or too
expensive for occasional hobby use.

Thanks everyone for responding so quickly to my search for schematic and routing software. I have downloaded the Eagle software, and am in the middle of contemplating stepping up one level to the non-profit version, so that I can deal with four layer boards and get a real manual. I find that it's parts library to be a bit helter skelter for me - so I will have to build up one of my own based on my normal preference. Maybe once I get to know the software a bit better I'll seek a list for it.

Ok, as a straight answer, it was unwise to force the thread, but you knew
that already. If there was any foreign body to restrict the threads,
excessive force would only serve to damage the components. Such tactics are
truly 'last resort' to get you home in an emergency. If you're sure the
threads are clean and compatable then the application of a lubricant may
help. I often find this with dissimilar metals, titanium being a major
culprit for 'grabbing' dry inserts.

Joe,

Interesting. A splitter as directional coupler for the reverse direction.... Hmmm Yea... and since the device 'probably' won't be near 75 ohms, that directivity won't be a big issue. What about the phase response bandwidth? That's important too. Unfortunately the phase response starts changing well into the passband, right?...

Hi all,

In his very skimpy explanation on basic DC biasing for FETs, Chris
Bowick (in RF Circuit Design) gives the suggested bias network that
I've posted to a.b.s.e under the same subject title as this message.
I don't see how this arrangement can possibly work for any N-Jfet
since for one thing at least, the gate is positive with respect to the
source. I've tried to scan the page in and post that, but the
scanner's messing about, so I've redrawn it as a spice schematic and
posted that instead. If it turns out the arrangement is incorrect, as
I suspect, I will endeavor to post his explanation for how he arrived
at these resistor values.
So: is he wrong or am I nuts?

p.

Note: for anyone using LTspice, the fet shown is not a working model;
I'm simply posting this as a diagram for illustration.

That was my impression. You'd have to use an external directional
coupler to do reflectance measurements.

Looks like the jfet will be saturated with the values shown, not good
for RF work. Looks like he got the sign of Vgs backwards. The next
example on the same page illustrates that Vg must be near zero, not
+5. Really silly, putting these two circuits side-by-side.

John

Oh, the skin depth equation on p 10 is apparently wrong, too.

Excellent, John. Many thanks. It's reassuring you've seen the actual
book for yourself, but it would have been better if you'd have hung
fire until Active8 or someone else impulsive jumped in and accused me
of getting it all wrong. There are quite a few stoopid errors in this
otherwise excellent book. This one was just a bit more obvious than
the others. :-)
Thanks again for the prompt response.

Well it was a neat idea in principle, certainly. Let's see if there's
a workaround for the issues you raise...

I have searched for info on these amps and found nothing. If you do
come up with a schematic, I would like to get a copy. Tune up info
would also help as mine has been "modified".

Hi Paul,

Seems like it was meant for a MOSFET or someone typeset a wrong resistor value and then all this got lost in the review process. Probably best to let the author know so he can correct in the next ed.

>>What is now proved was once only imagin'd." - William Blake, 1793.

I like this one! It reminds me of a mechanical engineering book I got from my late father in law, a book he received from someone even more senior. Under radio frequency waves it states that this is a wonderous and strange phenomenon that is yet to be explaineth. And here I am an RF guy...

Regards, Joerg

I never bought into that "only using one tenth" concept. It's a pretty
complex thing and I always thought that those who said that really didn't
understand what it is doing.

You can tighten slightly the nut on the screw then tap the around sides of the nut freeing off the thread. next tighten down again and repeat until sufficiant thread is compatible with the nut.

BTW... don't change the nut for another.

You also want to make sure that the resistors you use are suitable for HV --
Digikey and others sell 'em specially suited for this purpose -- carbon
composite resistors change value above a few hundred volts.

Most people think of a directional coupler as a directional coupler, and a splitter as a splitter. In reality, the splitter is simply the extreme case of a directioanl coupler where the coupling factor is 50%.

The fact that it was designed for 75 ohms is somewhat incidental. The impedance on any of the ports is a function of the impedance on the other ports. As to phase, it has to be well-behaved or you wouldn't have good directivity.

Not to the extent that you fettle it.

Correct practice is, wire brush away corrosion if heavy, lubricate, turn the nut, back off the nut, turn, back off, etc.

However, materials in the antennas your refer to rarely corrode if not used.

Face the truth Gareth, you just screwed it. Didn't you. Just like Westinghouse.

I see another Gareth disaster.

Do you know that Paxolin and Tufnol are not the same thing and both likely
to be lossey if used outside?

There's a cosntruction article by K2AOP on page 67 for a xtal osc that sounds appealing to me. ARRL says it couldn't measure the phase noise because its lower than their equipment. I wish they would have stated how low their eqpt goes as I was lead to believe they had some of the best. Anyone have any ideas?
tnx

They can usually get down to -160, -165 dBc/Hz depending on which cheek they hold their tongue in. I now wish, they'd get me my copy here. Don't often see a construction article in the rag. Do they take the output from the crystal using it as the "final" filter?

They have an HP 8563E, if I remember right. The analyzer's local
oscillator runs in the multi-GHz range, even for HF measurements, so it
wouldn't be economical to clean it up enough to measure a crystal
oscillator directly.

They still could have measured the performance, but it'd be a pain in
the neck, which is probably why they didn't bother. One way to do this
is to mix the oscillator under test with a second crystal oscillator of
known (very high) spectral purity, filter the resulting carrier out with
a high-Q notch filter, and look at what's left at a more-sensitive
analyzer setting than would otherwise be practical. This process has
quite a bit of room for error.

What I do is half a turn, back a quarter, and then repeat,
rather in the style of tapping a screw thread, using Rocol
also in the same style.

In this case, after 3 1/2 turns I reached the obstruction,
and retracted to examine. There didn't appear to be any obstruction
in the thread, although it was difficult to see because it was down
an aluminium tunnel, and so I applied greater force for the next
half turn, at which point it jammed up, and so reference to
this NG!

Odd that even a direct practical and technical question such
as this matter brought so many of the resident CB types out
of the wood work to sneer 'n' jeer on the sidelines. Their
behaviour in this public forum perhaps does more to create
a bad press for HamRadio and to lower the standards
than they perhaps realise?

Steve,
The unit performs reflection measurements using the internal
directional coupler, the dynamic range is maximum 30 dB. For
transmission measurements is necessary to add a second connector and a
switch. By the switch we can change the type of the measurement from
reflection to transmission.
The switch will change the signals path of AD8302 inputs, for
transmission measurement the directional coupler will became a power
splitter (-15 dB to the first AD8302 input and the rest to the actual
BNC connector-TX). The reflection port of the directional coupler will
be terminated to 50 ohm only, meanwhile the second AD8302 input will
be connected connect to the extra connector (RX). The software for
transmission measurements is not yet ready but I believe shortly I can
post.

I always thought I was last on the QST delivery line. It says its a Pierce
with a gate follower buffer for output. Quite stable and constant output!
It uses 2 2N5460s. I need to find a half dozen 2N5460s so I can build at
least a couple to test receivers.. If someone finds a source please let me
know. Also it someone builds and measures the phase noise please let us
know.
tnx

That's certainly one highly useful piece of artillery for the RF
designer!
I don't think it actually allows one to *extract* S- parameters
through modling a BJT, for example.
I haven't had the chance to check it over in detail yet, but it seems
you have to insert already predetermined S-params from datasheets or
wherever and it will generate matching networks from there. So it
doesn't actually amount to a 'virtual VNA' - or does it??

The 1st Amendment guarantees only that the Government won't imprison,
torture, or otherwise go after you for voicing your opinions. It makes
no guarantee that
someone ELSE might not kick your ass for it. I hear all this whinning
all the time regarding the 1st Amendment. Linda Ronstadt found out
about the 1st Amendment when she got kicked out of a venue in Las
Vegas a few weeks ago for voicing her opinion. Whoopi Goldberg (is she
a Jewess ? Is her name really Whoopteesha ?)learned about it, too, as
did Mike Moore. Sure , you can say whatever you want, but be prepared
to pay the consequences.

Good point. Bowick seems to be applying the jfet gate-voltage equation
backwards to enhance it! The other example on page 120 is even
sillier.

Just shows you that an RF expert can't always handle DC.

If you draw a part as a lumped equivalent schematic (ie, a Spice
model) it will give you the s-params. If you are very lucky, the part
manufacturer will give you that Spice model; few do.

>I haven't had the chance to check it over in detail yet, but it seems

I don't entirely know what you mean by that. It will give you the
s-params of a given simulated network.

The really hard thing is to have the s-params and go backwards to a
lumped Spice model. There is some software that does this, but I don't
know of any that I can afford.

This one I've downloaded doesn't seem to. You can select and join-up
lumped elements but there's no provision for inserting a transistor
model anywhere I can see. You can only construct a test circuit from
passives and one (dys)functional op-amp model only. A most curious
omission. I'd have thought there'd at least be the facility to import
a BJT spice model for a tranny or FET but I can't see any! :-/

Unless I'm missing something; only if it consists of passives.

I have a pamphlet with schematics of all of the BL amplifiers, but the
PA15-80BL is not among them. There is one for the PA10-80BL, which is
probably close enough because all of the amps use similar circuits.
I can scan it for you, although the copy that I have is not all that great.

Please reply direct.

Do you have the original edition ca. 1983, or what amazon.com descibes as the Newnes Reprint edition of 1997 ?

I too have seen mistakes in the 1983 edition. It would be a pity if these were not corrected in the reprint. Does any body have good information on this ?

Thanks and 73

Sure Joe,

you are right. I just never thought of it on that light.

Lets think about this phase thing, however. As long as there is the proper phase cancellation _in_ the splitter, it will balance. This doesn't mean that it is flat, does it? You'll be sampling the forward power somehow and the reverse power with one of these and you need to have them both constant with respect to each other--otherwise you cant measure phase.. If the fwd sampler is the same thing do you get matching characteristics (ignore secondary imperfections for now). I don't know how good ones are made, so I have know first hand knowledge.

1693. development of the "Desert Ratt" regenerative receiver design

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-08-12 20:51:00 UTC
From: n1jpr@hotmail.com
Message-ID: <95a201e0.0408121251.6c6e6e85@posting.google.com>
Source record: 24024

The "Desert Ratt" is a clever design for a sensitive and well behaved shortwave regenerative radio. It has been doing the rounds in various forms since 1994, and quite a few people added new twists.

As I kept seeing roughly the same stuff popping up all over the place, and found it somewhat hard to keep track of which version was an improvement over another one, I did a bit of investigation to figure out who did what, and what the direction of development was.

Read it all at:
http://webfools.net/filippo/desert-ratt.html

I am confused. Are you describing YOUR unit or the one first referred to.? I hadn't looked at your design, if it is on the web site. I was referring to the Robert Lacoste site. That block diagram has no dir coupler shown, just splitters, so it looks like a through measuring device only. Am I off base somewhere?

Let's assume for one moment the splitter idea would function
acceptably as a directional coupler for this purpose. What's next in
the block diagram? Phase comparitor? DC amp?

> Looks like the jfet will be saturated with the values shown, not good
> for RF work. Looks like he got the sign of Vgs backwards.

Well, when you rearrange the Id eq to get Vgs, you get

```
[ ]
| |
| ( ) |
| | I | |
| | D | |
V = -Vp| sqrt| ------- | - 1 |
GS | | I | |
| | DSS | |
| ( ) |
| |
[ ]
```

You can swap the terms inside the brackets by moving the negative
sign of Vp inside, which gives you Bowick's version. Either way, you
get the wrong answer unless you recall that

sqrt(4) = +/- 2

So you have to apply some reasoning.

Thus (3 dots in a triangle) Burridge = idiot^100.

Otay. You write the node eq for Vgs, expand Shockley's eq., equate
the two, rearrange, solve the quadratic and pick the correct root.

Sorry I thrashed around on that.

Paul & Steve,

Steve,
I'm pretty confident that the phase shift will be constant and can be calibrated out. If not, it can be made irrelevant by using two splitters, one for the forward path sample and one for the return path sample.

Paul,
The idea is to use the splitter 'backwards"; drive the RF into one of the splitter legs and feed the load through the common port. Assuming good directivity, any RF coming out of the other splitter leg must be reflected energy. If you put a sample of the forward energy into a scope's X input (horizontal) and a sample of the reflected energy into the Y input (vertical), you will get an elliptical display called a Lissajous pattern. If X and Y are equal in magnitude and exactly 90 deg out of phase, this will be a perfect circle. Any other phase angle will result in a elliptical pattern whose inclination angle relative to the X axis (or Y axis) is a function of the phase angle. The length of the ellipse is a function of the magnitude. This is classic stuff...look it up if you're not familiar with it.

Based on some recent posts, I suspect that duplicitous white trash POS is reading my posts despite his blasting JT for "not sticking to his [ctrl-k] guns" just to see what I'm saying behind his back. It's not really backstabbing since it's out in the open and I'd say it to his face before I rearrange it like so much algebra.

I think he needs a good old fashioned hillbilly ass-whoopin' what with the way he's flaming a few of us and making hillbilly slurs.

Apologies again for the multiple replies to self while working this out. That Siliconix book used design curves and iterative stuff.

I'd be impressed if SFB Burridge (rhymes with porridge - like the space between his audio sensors) could solve the bias net (or any net) on his own.

Theres no problem getting 10mA to flow in a FET with Idss of 5mA. Just
apply a positive bias to the gate. I've had as much as 2 or 3 A flow
through a JFET this way.

One model of Seymour Cray's computers ran with the logic immersed in
a bath of chilled Fluorinert or some such, with a fairly hefty pump
to keep the coolant recirculating through the chiller.

Sipa

Thank you for the nice links. Although the language is something of a barrier over on this side of the pond, "Foto-galerija" isn't so tough to figure out <g> Looks like a pretty town.

A single frequency receiver should be fairly simple to build. Unfortunately, most of the really simple things you see online are transceivers, and those are typically for 7 MHz, which is a slightly different problem than 27 MHz.

If you don't need a lot of sensitivity, and since you are interested in receiving CW, you may be able to rip off one of the many designs that use a VXO and a 602 mixer in a direct conversion design. I haven't personally built such a thing for 27 MHz, but I have had some success at 21 MHz with a dirt-simple design.

One challenge you will have is that the simplest designs rely on a crystal for your receiving frequency. These need to be custom made and as a result are fairly expensive (around 12 euro). An alternative is to use a programmable oscillator. These are a lot cheaper (under 3 euro) but are far from ideal for a receiver. Nevertheless, if you don't have strong stations nearby your channel 12 signal, it might be useable. Again, I have made this work at 21 MHz, but it is far from perfect.

One confusing factor ... the NE602 mixer, which is very popular for this sort of circuit, has undergone a number of changes in manufacturer and testing protocols. The result is that, although the circuits usually call for an NE602, you usually can't get one of those. However, the NE602, NE612, SA602 and SA612 are all the same part. The 604/605/614/615 are the same part with some extra stuff on the chip that you don't need to use.

You might put some sort of filter in front of the 602, but basically your antenna goes into the 602's RF port. The crystal or programmable oscillator goes into the LO port, and the audio out is taken into an amplifier chip like the LM396 or 380. The only hard part is that you need to be a little

careful about lead lengths because both the 602 and the 396 have astonishing amounts of gain and want to oscillate if you look at them the wrong way!

If you rummage around on the web, you will probably find hundreds of receivers with this basic model, although not for 27 MHz. All you need to do is recalculate the stuff between the 602 and the antenna for 27 MHz instead of the frequency for the model you find. You will want more gain at 27 MHz than for 7, so you may want to take a look at the 396/380 combination that Elecraft uses in the K1 instead of the lone 396 that many designs use, depending on how much audio you need. My 21 MHz receiver using only a 396 was pretty marginal, although useable.

The other issue with the 602 is that it is prone to issues with nearby signals. In western Europe this is a big problem at the lower frequencies where the airwaves are very crowded. If you have plenty of strong signals close to your channel 12 signal you may need to go to a different approach. The problem is that the passive mixers that work well in this environment do require additional circuitry, which is significant when you are aiming for as cheap and simple as possible.

Hope this helps a bit

..

You guys seem too negative. I know I was pointing out difficulties, but
only to keep the limitations in mind. Actually, it ain't that wacky. It is
EXACTLY how the Professional equipment does it, just with really good
couplers etc... As long as the phase and magnitude can either be controlled
or known and calibrated out, it should be pretty good.

If you have a scope that can go to the frequency of interest, you have a
really good basis for success.
The one thing I couldn't get fixed in my mind is the phase considerations of
using one splitter for forward sampling and one for reverse. Two things to
consider are:
1- As the freq gets higher, the phase of the FWD sample and REV samples get
"further apart" since they can not be at exactly at the same point on the
t-line, namely the load. Therefore, you have to adjust the line lengths to
'move' them to the same virtual point. Perhaps at HF this is a don't care.
I'm used to doing this @ > 150 MHz.
2- If you are in a region where there is a phase change with frequency in
the splitter/coupler, are you sure that it is the same in both directions,

or does it not work that way and will it work to increase the error rather than both of them tracking together. I just can't model this in my brain without putting some things on paper... I guess, with the scope, you can examine that and make adjustments for it by using "calibration loads" just like the calibration kits used by the pros.

I still believe the Lissajous (I'm sure glad you can spell that) method is not as good as simply measuring phase shift between the two signals directly in normal scope mode. With the Lissajous, it is harder to get the magnitudes equal and then measure random angles from the "tilt" of the oval. Don't the Lissajous formulas all assume equal magnitude sine waves? You'd have to compare amplitudes in normal mode and adjust the vert gain to set them equal anyway, so why not just set the horizontal sweep speed for a 'nice' speed and then the shift is on a calibrated scale. 9 divisions for a 1/2 cycle and you have 20 degrees per cm and the little divisions are 4 and you estimate from there. This way the phase measurement is almost 100% independent of amplitude 'cuz you're looking only @ the zero crossings. I don't think you can estimate 4 degrees on a Lissajous that easily.

I still wonder WHAT kind of transistors the OP wanted to measure...

Jfets make pretty good pA-leakage diodes, although the series
resistance tends to be higher than for a "real" diode. Never tried one
as a power rectifier.

Jfets don't enhance much, but gaasfets - especially phemts - enhance a
lot, typically 1.6 * Idss just before the gate begins conducting in
earnest. That can be useful.

Steve,

I'm making this up as I go along and I haven't actually tried it, so I might be off here and there. I already realized that my previous explanation of how the Lissajous pattern should be interpreted is wrong. I think it's more like this: Two signals (X and Y inputs to the scope) with equal amplitude and phase signals will produce a straight line with 45 deg inclination. Varying the magnitude of the reflection signal (assume it's on the Y axis) will move the inclination angle of the pattern up and down. Any phase difference will cause the line to open up into an elliptical shape, where the "eye opening" of the ellipse is proportional to phase difference. At 90 deg, the ellipse will be perfectly circular. Let me know if that explanation holds water better.

> like the calibration kits used by the pros.

Well, in as much as physical distance is time-delay and time-delay is phase, you're correct. However, the physical distance of each leg can be made equal, leaving only the circuit phase as an error source. I believe that the splitter should have equal phase response in both split ports (relative to the common port), otherwise you couldn't get the perfect amplitude and phase cancellation that gives rise to directivity.

I agree with you. The Lissajous thing popped into my mind because it's a classic. I'm not sure it's the best. Important thing is the concept that you can decompose the signal into incident and reflected components with a directional coupler (or splitter), analyze the components to determine relative amplitude and phase, and then mathematically derive any 2-port metric you want.

The fly in the ointment is that scopes typically don't have very high
bandwidth (more than a few MHz) in X-Y mode. The X-axis amplifier
section of even a relatively-fast analog scope like the 2467 is only
rated at 3 MHz, and you'll probably get significant phase shift long
before that point is reached

Well there is some rule for 27 mhz CB transcievers. we don't need exams and similar but we must compleet some forms and send them to agency for telecomunications. in form we must write "origin of device" and type/model for homologization. Then they send us a "licence" and with that licence we dont have problems if police controls our car (with cb radios) in croatia and out of croatia, or similar...

But, form pmrs, lpds or similar any registration are not needed.... (eu laws)

What kind of "CW"? Keyed carrier or modulate tone (MCW)?

The simplest receiver you could build would be a superregenerative,
as was used in simple handhelds sold in the early 1950s. That would
work fine for MCW type signals, but would not do for keyed carrier
CW.

For sure, you shouldn't use an analog scope for this, for the reason John gives. In an analog scope, both the vertical amplifiers and the vertical CRT deflection system are optimized for speed, but the horizontal aren't. Even if you use identical amplifiers for X and Y, the horizontal CRT deflection structure will limit the X bandwidth, and give you considerable phase shift well below the cutoff frequency.

Modern digital scopes, on the other hand, should work equally well on the two axes.

> information. Much appreciated.

I believe that it uses the same protocols as the Spectracom
8170, which is well documented in many places including the NTP
source code. From refclock_wwvb.c:

```
* This driver supports the Spectracom Model 8170 and Netclock/2 WWVB
* Synchronized Clocks and the Netclock/GPS Master Clock. Both the WWVB
* and GPS clocks have proven reliable sources of time; however, the
* WWVB clocks have proven vulnerable to high ambient conductive RF
* interference. The claimed accuracy of the WWVB clocks is 100 us
* relative to the broadcast signal, while the claimed accuracy of the
* GPS clock is 50 ns; however, in most cases the actual accuracy is
* limited by the resolution of the timecode and the latencies of the
* serial interface and operating system.
*
* The WWVB and GPS clocks should be configured for 24-hour display,
* AUTO DST off, time zone 0 (UTC), data format 0 or 2 (see below) and
* baud rate 9600. If the clock is to used as the source for the IRIG
* Audio Decoder (refclock_irig.c in this distribution), it should be
* configured for AM IRIG output and IRIG format 1 (IRIG B with
* signature control). The GPS clock can be configured either to respond
* to a 'T' poll character or left running continuously.
*
* There are two timecode formats used by these clocks. Format 0, which
* is available with both the Netclock/2 and 8170, and format 2, which
* is available only with the Netclock/2, specially modified 8170 and
* GPS.
*
* Format 0 (22 ASCII printing characters):
*
* <cr><lf>i ddd hh:mm:ss TZ=zz<cr><lf>
*
* on-time = first <cr>
* hh:mm:ss = hours, minutes, seconds
* i = synchronization flag (' ' = in synch, '?' = out of synch)
*
```

```
* The alarm condition is indicated by other than ' ' at a, which occurs
* during initial synchronization and when received signal is lost for
* about ten hours.
*
* Format 2 (24 ASCII printing characters):
*
* <cr><lf>iqyy ddd hh:mm:ss.fff ld
*
* on-time = <cr>
* i = synchronization flag (' ' = in synch, '?' = out of synch)
* q = quality indicator (' ' = locked, 'A'...'D' = unlocked)
* yy = year (as broadcast)
* ddd = day of year
* hh:mm:ss.fff = hours, minutes, seconds, milliseconds
*
* The alarm condition is indicated by other than ' ' at a, which occurs
* during initial synchronization and when received signal is lost for
* about ten hours. The unlock condition is indicated by other than ' '
* at q.
*
* The q is normally ' ' when the time error is less than 1 ms and a
* character in the set 'A'...'D' when the time error is less than 10,
* 100, 500 and greater than 500 ms respectively. The l is normally ' ',
* but is set to 'L' early in the month of an upcoming UTC leap second
* and reset to ' ' on the first day of the following month. The d is
* set to 'S' for standard time 'I' on the day preceding a switch to
* daylight time, 'D' for daylight time and 'O' on the day preceding a
* switch to standard time. The start bit of the first <cr> is
* synchronized to the indicated time as returned.
```

Tim,

thank you for your response. This clock does not receieve the WWVB signal
directly, instead it is inputed via a WWVB receiver. The receiver that
can be used are the 8160,8161, 8164, and 8165. At this point I guess I need
one of those receivers.

Many years before, IBM was going to use a CFC (FC86, IIRC) in much the same way. The logic modules were about 4" cubes with a multi-layer (50-60, can't remember) ceramic substrate with 100 logic chips on one side, a water-filled cold-plate on the other, and filled with the CFC. Heat was removed from back-side of the chips by boiling the CFC. I worked on a logic tester in '75 that immersed the un-encapsulated substrate into a bath of CFCs so it could be probed.

Unfortunately, boiling the CFC also distilled it, leaving any contamination on the chips. The result came to be known as the "black plague". Because of the "black plague" the "LEM" (Liquid Encapsulated Module) was replaced by a similar looking (though shorter) "TCM" (Thermal Conduction Module) which used pistons on the backside of the chips (increased to 121 chips) to transfer heat (>10W per chip, 1200W total) to the cold-plate and filled with helium. The TCMs were used throught the '80s and early '90s for the high-end ECL systems.

1744. D104 and the 706

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-08-14 17:16:40 UTC
From: pdrunen@aol.com
Message-ID: <20040814131640.12089.00003510@mb-m01.aol.com>
Source record: 24076

Hi Group,

Got a 706 which has a 500 or 600 ohm mic input impedance. I have a D104 which best I can tell has a high output impedance.

If I use a 60Hz step down transformer, say, 120V in gives 10v out, the turn ratio is 120/10 or 12:1. Given that I attach the mic output to the primary and the rig on the secondary, this should step down the impedance by a factor of 12^2 or 144 so that a D104 with 50K on the output is now seen as about 400 ohm.

Here are a few questions,

1: Will a 60Hz transformer work well keeping the base sound and pass upto 3KHz?

2: Is the calculation of the impedance correct?

3: Would the audio as seen on the secondary be reduced by a factor of 12 such that the audio would be weak?

4: Other?

Tnx de KJ4UO

Sulfur hexafluoride might have been better, but it's probably more
costly than CFCs were.

Yep. I've got a TCM somewhere at home; I need to take a pic of it
for my web page. IIRC, it has 1024 pins, and the largest ZIF socket
I've ever seen. The cold plate on the TCM is about 4.5" square, very
smooth, and designed to go on a larger water-cooled manifold with some
dozens more TCMs, all getting water from a chiller.

They're called "wet-frame" machines by a lot of us who dealt with
them, and especially by those of us who had a leak develop somewhere
in the cooling system.

Nowadays one TCM's circuitry fits on a single chip, at a meager
fraction of the TCM's dissipation, and is enormously faster, so that
(for 9672 hardware, anyway) IBM ships the machine with a bunch of CPUs
and licenses you the code to turn on as many as you're paying for. If
you want more than ship in the base machine, they'll install another
dozen pretty cheap.

And the homebrew and design connections:

They're sure not homebrew, and they're more than one designer can do.

Cost? Dunno. I do know that we were paying $50/qt (IIRC) for the stuff
in '75. I wouldn't think a sulfur/fluoride brew could be made any
"cleaner" than CFCs. THe problem was the contaminants.

I think you'll count a lot more than 1024 pins. The ones I worked on int the '70s had 1800. There were 1280 signal pins (I rember that name because of the logic tester - the LT1280).

> The cold plate on the TCM is about 4.5" square, very

Twelve TCMs for each processor, and nine for each channel (for the 3080s). A system could have upwards of a hundred of these beasts in it. Later sytems had fewer since the logic density increased. ...which is what ultmately killed them. The infrastructure was simply too expensive for the quantity needed.

> They're called "wet-frame" machines by a lot of us who dealt with them,
> and especially by those of us who had a leak develop somewhere in the

Pissers, eh? I was once tasked to design a "leak detector" for exactly thi sproblem. I brought in the guts out of a toilet (complete with copper float) and told them to put these under the floor with a switch. Come on! Detect a leak in a pipe a few hundred feet long passing many gallons per minute?

> Nowadays one TCM's circuitry fits on a single chip, at a meager fraction
> of the TCM's dissipation, and is enormously faster, so that (for 9672

Note that the first CMOS machines were slower than those they replaced (in direct violation of IBM's "prime Directive"). THough they were significantly cheaper and with more processors (loophole alert).

> IBM ships the machine with a bunch of CPUs and

"Install"? ;-) They'll enable as many as you want, for as long as you are paying. We called this "Rent-A-MIP". THere is even a crypto unit in there if you want to use it.

> And the homebrew and design connections:
>
> They're sure not homebrew, and they're more than one designer can do.

Yeah, there were a few designers doing this stuff. ;-)

Yeah, and whether you're working with a liquid or gas, it's the contaminants
that make it dirty. I'd think a gas could be cleaner already just by not
dissolving a bunch of solids, although the solids in suspension can be
even smaller than in a liquid. But those aren't going to condense out.
They might collect as dust, but if that's your problem, then you have
a lot worse problem than contaminated fluid!

I guess my point is, it wasn't the CFC's fault that it was contaminated.

And, FYI, AIUI, SF6 is really quite inert. You make it sound like fire
and brimstone, for heaven's sakes! ;-)

But it has raised a good question - which makes a better heat transfer
agent? Helium or SF6? (gases only, of course ;-))

Cheers!
Rich

I'm no transformer expert, but the transformer you mention may be kind of lossy for an audio application. I would look for a suitable audio transformer at
www.mouser.com . I believe power transformers are wound using larger wire and forms, and are designed to be efficient at their operating frequency of 60Hz....

You could use a simple op-amp buffer circuit, with a resistive
attenuator to knock the voltage down if necessary. Even with the 9V
battery to power the thing it'd be no larger than your transformer, and
would certainly give better audio than a power transformer.

That part was produced by CML (formerly MX-COM) for commercial two-way radio use. It's no longer in production, so your best chance is to ring up the local two-way radio sales/service shops and ask if they have one in spares. As I dimly remember, the going price in the USA in production quantities was about $6, so you may expect quite a bit higher.

Data sheet is here:

1758. Re: development of the "Desert Ratt" regenerative receiver design

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-08-15 06:39:55 UTC
From: The Eternal Squire <eternalsquire@comcast.net>
Message-ID: <ndidnZSKG42nmILcRVn-vw@comcast.com>
Source record: 24090

SpamHog,

Here's another question:

I've been building the Desert Ratt 2 today, starting with the audio amp. Problem is that I am getting attenuation rather than amplification.

I have questions about the biasing network surrounding Q4. R9 and R10 are specified as 1.2K (1200 ohm). The schematic states that the emitter and collector voltages should be 3.0 Volts. However, my version develops an collector voltage of 7.2 Volts and an emitter voltage of 1.7 Volts. My base voltage is 1.8 Volts (which is in the ballpark of what the schematic states as should be 2.0, I am not nearly as worried about that one.

I had used a 2N3904 as recommended. On the assumption that the transistor could be bad, I subbed a 2N2222. Same result.

It seems to me there might be a misprint with respect to the values of R9 and R10.

Any ideas?

Hi all,

Anyone got any high-current/low-voltage horror stories they'd care to
share? You know; where your messin' about with a car battery or
something like that and forget to take your watch off or whatever.

My brother, circa 1965, was working on a six volt Chevrolet.

His ring got between the battery terminal and ground. (Don't ask me how.)

He ended up with a destroyed ring and a finger with a very painful burn around it.

No permanent damage but come to think about it he's a little weird even today. Hmmm.... but isn't everybody weird but you and me and I sometimes wonder about...

==========

This is really not low voltage high current but an event that sticks in my mind as potentially fatal.

I had a female student in one of my community college electronics class. The electronic bench where she was working had a 8 foot strip of outlets on one of the typical 1970s surface mount plug strips. She had plugged in some instrument but in retrospect she hadn't pushed the plug in completely, leaving a small amount of the metal of the plug exposed.

Around her waist she had a silver colored metal belt with a hanging end with a washer shaped end on it. It looked to me like a dog collar.

She bent over the bench to adjust something and the metal end of her belt went across the metal prongs of the plug.

RESULT = lots of sparks, a loud scream, a partially melted end to the belt and a much wiser and more careful student. (And a very relieved instructor, thankful that it hit BOTH prongs and not just one while she was holding touching a grounded instrument case.

Yes, we then moved all the plug strips on the benches where they were mounted to the bottom edge of the bench and removed them from other benches where there were adequate outlets on the plug strip on the front of the shelf along the back of the bench.

The place was Hong Kong.

It was around Xmas, 1945.

I was alone in the lab.

Working on a set of airborne radar equipment strewn around the workbench.

The scanner was not rotating, just pointing out of the open window, past a Royal Navy cruiser moored in the harbour about a mile away and onwards to Victoria City with the island's mountainous peaks in the background. All displayed strong echos on the PPI on its 10-mile range.

As indicated on the PPI there was something intermittent.

I suspected a poor coaxial cable connection.

Familiarity breeds contempt.

Forgetting the equipment was still switched on I unscrewed one of the many coaxial connectors and Pye plugs.

To clear out any foreign bodies I inserted the tip of by my right forefinger into the vacant socket.

Now that particular socket was power output from the modulator unit on its way to the transmitter unit. The transmitter was a 50 Kilowatt magnetron which required unpteen thousand volts, pulsed at several hundred times persecond with a one microsecond pulse width.

How long I lay on the floor I do not know. Probably only a few seconds.

I trembled all over which passed off after a few minutes. Apart from a white burn on the afore-mentioned fingertip the after-effects were sychological - it took several days to pluck up courage just to re-enter the lab when I had difficulty looking in the direction of the offending plug and socket.

Part of the mission of the National Traffic System, which is part of
the ham radio community's emergency preparedness and operations
efforts, is to pass "health and welfare" messages in times of
disasters.

Contact a member of a local radio club about sending a radiogram to
your friend. Keep in mind that this type of message is lower in
priority than others, and that his being in an emergency shelter or
utilities being down will slow it down.

There may well be hams doing direct contacts with hams in that area,
but the last step of getting the message to your friend may be a
problem.

Happy trails,

Well there was this guy changing batteries on a golf cart.
Had 6 very large 6 volt storage batteries wired in series.
He was using a ratchet wrench to remove the battery contact
clamps and while detaching the most postive end first (!)
the ratchet handle touched the frame of the golf cart.

Ever see a Sears ratchet glowing WHITE HOT?

Though there is considerable voltage involved in the production of the
currents involved, it is the (forces of the magnetic field of the)
current that crushes the coins.

My dad (the first W3DHJ) told me an almost identical story.

It was in the late 20's. He was working on _his_ dad's Ford utility truck. (Grandpa owned a dairy in Big Bear, Calif.) Six volts here, too. The truck was parked in the driveway -- just outside the garage. When my dad caught his ring between the positive terminal and the truck frame, my Grandpa picked him up bodily -- ran him over to the rain barrel at the corner of the garage -- and stuffed my dad's entire left arm (and much of his upper torso) into the barrel.

(*The worst* thing you could do in a situation like that is try to _pull_ the ring off.)

My dad was a 90-day wonder in WW II. He then spent 25+ years in the U.S. Army Corps of Engineers (we traveled the planet....) Most of his duty assignments were as (Deputy) Post Engineer -- with the added responsibity as Post Safety Officer. I always knew him to be evangelically anal about safety. I'm sure that incident with the old Ford truck had a wee bit to do with it.

The SATERN net has been reporting on conditions in various places, but H&W traffic isn't going into the area yet as far as I can tell. (Shouldn't be a surprise if you think about it). However, if you go to www.satern.net there is a link at the bottom of the page to a form where you can inquire about an individual. Supposedly this is faster than sending a radiogram.

However, if you want to try some traffic into the area and you don't know how to get into a local traffic net, you can check the ARRL website for section nets in your state, or you can try the ISSBN at 0100Z on 3.985. If you are a little rough on traffic procedures, the ISSBN may be a little more tolerant than a section net, depending on your particular section. If you are not an amateur, and the SATERN website doesn't look like the ticket, then Gary's advice is the best you will get.

I did once work with this sort of power, at a company which was making
superconductors. We had to test various samples at high current/low
voltage to determine some of the properties, while they were submerged
in various liquified gases.

One project involved setting up a two-module 1000 watt DC power
supply. I "wired" them together using copper bar stock 1" by 1/4",
bent to fit the terminals, and plated with silver for lower contact
resistance. The connection to the samples was with 2 ought welding
cable, which was about 1-1/8" in diameter with insulation.

I have also worked with high voltage RF up to 20 kV, but that is
another story.

The general rule is when you are working with KIL-o-amps, KIL-o-volts,
or KIL-o-watts, is to make sure you don't get KILL-ed.

> the schematic states as should be 2.0, I am not nearly as worried about
> that one.

The voltages on the schematic are wrong.
Whatever the base voltage is, the emitter
should be 0.6 to 0.7 volts lower. Then
you can calculate the emitter current as
Ve/Re (around 1 mA in this case). The
Collector voltage is approximately Ie/Rc
lower than the supply voltage, or something
around 7V here.

The fact that your emitter voltage is only
0.1V less than the base voltage says that
either the transistor is bad (which you seem
to have eliminated, you have a bad or wrong
value component, or a wiring mistake.

I'd suggest disconnecting C15, C16 and
C17 to isolate the stage, and repeating the
dc measurements.

==========
Don't know the D104 mic (Shure ?) However many socalled High impedence
microphones are dynamic low imp. mics. with a small transformer fitted
inside the mic. housing. Examples : Mics supplied with Yaesu valve
transceivers from the 1960 -70s.
By disconnecting the transformer it is just a 500 - 600 Ohms microphone.

Paul -

First, The D104 microphone was manufactured by Astatic, a division of
Omnitronics.
Omnitronics LLC
341 Harbor Street
Conneaut, OH 44030
http://www.astatic.com/

There are several models of the D104 microphone (e.g., stand combinations,
transistorized preamp, etc.) - detailed on their web site.
All D104 microphone that I am aware of ... use a high impendence
ceramic/crystal microphone element.

Wiring diagrams for the 8-pin Icom (not the RJ-45 jack version) is on their web site.

Some operator have switched the D104 to Heil dynamic elements (HM-4 or HM-5).
Astatic no longer has the crystal elements, but Mouser has a good Far East substitute.
http://www.mouser.com/

This make a big difference in your approach -- since some of these bases have a low-Z / high-z switch in the amplifier OR
actually have an audio transformer in the base for this purpose.
The Heil XT-1 is a suitable transformer, Mouser has several candidates in their catalog.
Radio Shack use to some suitable audio transformers for $ 2 or so.

Xicon has some candidates (e.g. Mouser # 42TM017; 42TM019; 42TM024) .. with differing input impedances (25K and 10K) and power capability (not a major issue for your application)

Digi has them as well, and I have some on order. Doubt there are any surprises, but hope springs eternal. Suspect that the "Tech Correspondence" dept didn't have the clout to get the attention of the lab. Will let you know in about a week.

The place was the same lab in Hong Kong.

There was a chinese lady who came in each day to sweep the floor and remove the EF50 valves, etc, which had been replaced because of low cathode emission.

It was my habit to point the radar scanner into the room, stand in the beam and quickly put put a neon lamp into my mouth. The lamp always lit up brightly.

Whenever I did this the lady used to run out of the room terrified at the magic sight.

Just the sort of trick a 21-year-old RAF radar mechanic would play.

Being in the Far East, the anti-radar defence rumour, spread by the Germans, that exposure to radar beams caused sterilisation to radar mechanics had not reached me.

Anyway, as my wife at intervals some years later allowed me to think, I eventually became the father of 5 children.

Reg

Remember an old article in popular electronic, back from 1960's,

young boy wanted to help his girl nextdoor with a wart on her hand,
bright as he was, he thought he could use the hv from his pops hf rig
to burn off said wart.... well, she let out this scream that almost
broke the sound barrier and he got his butt wacked big time.

The wart did get removed !

Perhaps you shoulda stood a bit closer to the waveguides, Reg. You'd
have been rich by now without all those kids. Plus you might even have
grown an extra brain. ;-)

there was an article in QST (circa 1992 IIRC?) on adapting the astatic d104 microphone using a single dual op amp, setup for 300 to 3,000 hz pass band, for impedance conversion to 600 ohms output impedance. Some d104 mikes had an adapter built-in using a 9 volt battery, one recently sold on Ebay ($21-ish) with the mike ;-)

1788. Yet another follow up.

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-08-16 03:06:57 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <cfp8cg$k71$1@sparta.btinternet.com>
Source record: 23920

The time was 1952 or 1953. I had a roving job. Indeed I've nearly always had a roving job. You meet people.

The place was Gretna Green, just a few hundred yards from the well-known black-smith's forge and its famous marriage-ceremony anvil.

I was working with a colleage in a normally unstaffed telephone repeater station. The job was capacitance-rebalancing of the multi-pair trunk carrier cables which ran through the place.

The test leads were very flexible twin-screened cables which kept getting in the way of the portable test equipment, on a collapsible table, and the two operators. Difficult to read the dB meters.

So to ease the accommodation problem the test cables were tossed up and over a pair of substantial bars, up near the ceiling, which could have been part of the station's equipment racks.

Unfortunately, the insulation over the screening braid was worn at one point and the bars turned out to be the main copper 50-volt bus-bars from the battery room. Work continued in silence until suddenly there was a loud bang, like a cannon shot.

The main fuse from the station's batteries had blown. The station stopped working. England was disconnected from Scotland at a time when the Cold War had started.

There was a glass-fronted fusebox containing a lot of cardboard-cased fuses. The idea was for fuses which had blown to indicate themselves by charred cardboard. But none were indicated although spare fuses were available. One catastophy after another. But in any case neither my colleage or I was familiar with station maintenance procedures.

We had visions of severe disciplinery action being taken. And I had brought with me a set of fishing rods. Indeed, I had obtained after much arguing temporary exclusive membership of Gretna Green fishing club at the then extortionate fee of 2 shillings and sixpence.

But then our luck changed. 10 minutes later the local maintenance man walked in. Purely by chance he had come in to make himself a cup of tea (facilities were available) whereas he should have been doing something else in the English town of Carlisle, 12 miles away. We were of senior rank. He fixed the fuse and we never heard any more about the serious incident.

In the evenings I went fishing for trout by bright moonlight while my colleage, a much older fellow than I, took my wife (who had come to join me for a week) to the local Gretna cinema. He bought her icecream in the back

row. And I made friends with the female cook at the hotel and had trout and butter for the first course at breakfast.

The next few jobs took me further into the wilds of Bonnie Scotland where there was nothing to do except to gamble and play cards in the evenings. I always lost. Even to the extent of losing my ex-army camp bed and having to sleep on the hard wooden blocks of the repeater station floor. Myxamatosis raged amongst the poor Scottish rabbit population.

It is only relatively recently, in my old age, have I returned to such happy days. I have just opened a bottle of Sierra Valley, Californian white wine for a night-cap. Diplomatic relations are now back to normal. I expect no more irritable invitations to tea parties in Boston.

Yours, Reg, G4FGQ

==========

Paul,

I could have been even richer if I'd charged for all those computer programs. But I have been much happier just by producing them instead of setting up a waste-of-my-time sales and marketing organisation. But it's a fact I never realised at the outset how popular they would become. I was under the impression I was a late-comer to the field. But it seems I was not. I was perhaps the originator of this type of program.

And I am confiding in you, even now, only because I am half-way down a bottle of Californian medium-sweet white. Must keep international relations in good order.

Yours, Reg, Amateur radio station G4FGQ

Use a direction coupler for forward and reverse measurement.
Use a 2 Chan. Scope great bandwith not nessesary, it is the amplitude that is to be measured.
reflection coefficient = Vreflected/Vincident = polar magn. and angle
Chris Bowick Book page 104, reflection coefficient may be plotted directly in the Smith Chart, and the corresponding impedance read off the chart.
Or did I missed something?

Yep. I had used LTSPICE to figure that one out. Collector and Emitter
DC voltages measured are same as on simulation, NOT on schematic!
AC voltages on nodes 3 and 8 from simulation agree with same on
schematic. I should measure the AC voltages.

Or I should report the emitter voltage more
exactly. I'll verify this. Tell me something,
how terrible an idea is it to use disk ceramic
for C15, C16, and C17? I have heard of
disk ceramics being capable of conducting DC
if made badly.

Thanks,

The Eternal Squire.

PS: LTSPICE is the ham's best friend! I
think it would be worthwhile to post the
entire SPICE file for the Desert Ratt 2,
wouldn't THAT be something!

In 1982, I was about 20 I guess and working for Dentron Radio as a tech. For no other reason than being careless, as I was normally on high alert when working on the amps, I discharged a fully charged bank of filtercaps in a Clipperton L from the left hand to the right.

I had tunnel vision for a couple seconds, fell to the ground as co-workers rushed to my side. Short of breath and dizzy I began to sweat profusely. I was ill for about a half hour then both arms began to ache as if I had been pummeled with a baseball bat.

I have been zapped a few times since then but never ever will I allow IT to flow across my chest again, that event scared the hell out of me and I was a strapping young lad in good shape. Today the same hit would kill me, I'm sure of it.

This could also explain my devout interest in QRP today!

Tim

This dates thirty years back: I was about ten years old. My father did occasionally charge car batteries in the basement of our house. The output of the charger was short cable with a broken cigarette lighter plug. He did connect the battery to be charged with a pair of jumper cables connected to it.
I was doing something in the room, when there was a big spark and some smoke started to appear. I immediately disconnected the charger from the mains as he explained to us that this was all we had to do to remove all electricity from a device. I then went to search for him to tell him what happened. When we came back the room was full of smoke and all what was left of the jumper cables was some melted plastic. The copper was all gone !

When I graduated from highschool, 1967, I started work for a company called Standard Plastic Products. What we really did was make those plastic and cardboard Barbie cases. These were heat sealed with RF Energy. Lots of it.

The work area had about 50 sealing machines. These units were Class-C RF oscillators and ranged from 25 to 60 KW. Yes, that is Kilo Watts. Each unit had a large ceramic tube that had a base of around 6 - 8 inches in diameter. The larger units had tubes with large heat sink hats which required a chimney to remove the heat. The RF energy was applied to two copper platens that performed the sealing.

My job, along with three other techs, was to keep these machines working. The most common problem with these things was blowing fuses, dirty coupling capacitor clips, and some pretty spectacular blowouts on the platens when the material got too thin.

The real problem was that, you had to reach into the units from the back to get to the fuses or the coupling caps. The units had power interlocks, so you couldn't activate with the back open This was suppose to disable all power, remove the plate voltage, and allow any charge to bleed off. But there were a few units where the bleeder circuits did not work properly. This usually left a few thousand volts on the plates of the tubes. You learned real quickly to grip your adjustable wrench with your cardboard fuse pullers and short the plate to ground. It was a heck of a blast and after 2 or 3 times, the unit was safe to work on.

Although I never heard of anyone actually comming in contact with the voltage, because we were always on our toes, but I am sure that it would have done some damage. I doubt the government would let them get away with something like that now.

And you want to talk about QRM, these things oscillated around 27 MHz.

The issue was that during the phase change the contaminants were left
behind. They were soluble in the liquid, but have a far higher BP than
85Cish so they're distilled *onto* the chips.
>
> I guess my point is, it wasn't the CFC's fault that it was contaminated.

I didn't blame the CFC. I don't "blame" inanimate objects. ;-) No
matter how clean the CFCs any trace contaminate deposited on the parts
that were boiling, exactly where you don't want the contamination.

> And, FYI, AIUI, SF6 is really quite inert. You make it sound like fire
> and brimstone, for heaven's sakes! ;-)

I tried to look up SF6's properties, but got nowhere. I don't think it
could have replaced CFCs. The particular CFC was chosen for its
precise boiling point.

> But it has raised a good question - which makes a better heat transfer
> agent? Helium or SF6? (gases only, of course ;-))

Note that the He was aided by pistons contacting the back of the chip
(C-4 mounted). It was a much different and more complicated package
than the LEM.

> Here are a few questions,

The other, more practical questions are answered by others, but:

> 2: Is the calculation of the impedance correct?

YES. Power remains the same on both sides of the transformer. If "V"
drops by a factor of X, the "I" increases by the same factor. R (or Z) = V
/ I

Z Pri = Vin / Iin
Z Sec = Vout / Iout
Vout = Vin / X
Iout = Iin * X
Zsec = (Vin/X) / (Iin*X)

= Vin/Iin / X / X
= Z Pri / X^2

> 3: Would the audio as seen on the secondary be reduced by a factor of 12

Yes.

> such that the audio would be weak?

The low Z mics have less output voltage than Hi Z mics and since you can
simply use a mic transformer to go between the two, you shouldn't have a
level problem.

I didn't look closely at this circuit, but the Pierce seems to have the crystal from plate to grid, or drain to gate. This seems as though it is easy to slam the crystal pretty hard (depends on the drain resistor). I'd worry about crystal dissipation as this causes drift and ageing issues. In VCOs, the more tightly you couple the tuned circuit to the device, the poorer the phase noise. We always had to get the things to just barely oscillate under worst case conditions to get the lowest phase noise. There are other ways, but memory fails...

I like the good old standby common collector colpitts used in just about all Motorola channel elements & oscillators. Hard to make one which won't oscillate.

Yup, much of what was said. You simply restated it, to some degree. We
were MUCH deeper...way past the basics.

The scope has to work reasonably well at the frequency of interest. They
can die pretty fast abofe their useful frequency.

You also have to measure *phase* between the two signals.

The disc ceramics should be ok, as long as they're
good.

I've never built this circuit, I'm just looking at it
as a paper exercise. DC measurements will usually
locate the problem. Spice may be overkill ;-)

==========

Paul, what makes you think I do a great job? Nobody ever tells me. It's not just idle curiosity. I'm not fishing. Feedback needed.

I always have several programs on the go at any point in time. Some have lasted, on and off, for years. But little to do with complexity. More to do with reliability and freedom from bugs.

I have an unfinished program which calculates the L and C values of a parallel tuned circuit. It can be connected in an antenna wire to resonate it to two frequencies. It is not a trap. The circuit's resonant frequency doesn't matter very much. But on the low side of resonance it behaves as an inductive loading coil and on the high side it behaves as a capacitance load. The antenna becomes resonant at one frequency below the wire's natural frequency, and at another frequency above the wire's natural frequency.

Unlike use of a trap, at both frequencies the wire radiates over the whole of its length. Furthermore, at its lower resonant frequency, the wire is shorter than a 1/4-wavelength.

I do not claim to have invented the arrangement. It has been previously discussed on a newsgroup. But I doubt if the L and C values have been explicitly calculated before.

I hesitate at making the program available to all and sundry for ever more, because I am unable to erect an actual antenna to prove the calculations correct. Although I am reasonably confident they are correct.

I use Pascal source code. Its an old language and you can't teach an old dog new tricks. But programming languages have settled down. There's little further room for improvement. I like Pascal because it is disciplined and structured. There's no such thing as a "Go-to" command as with BASIC. The compiler won't allow you to make logical mistakes. The quality of a program, the finished working product, doesn't have much to do with the language used. Chinese is just as good as English.

Agreed, and the statement about starting with ~2 volts indicates way too much feedback at 12 volts. Certainly none of the above leads one to think it's a low noise circuit, just going to build one to measure. Suspect that the "no free lunch" still applies and that to get really low noise operation you still need current limiting, AGC 'd or otherwise and tricks like feeding the output thru the crystal to clean it up. Also believe there's probably a contribution by the draftsman again and the 22 meg gate resistor is really a second 2.2 Megohm .

John

Your oscillator in QST sure sounds appealing. Just saw the feedback on the errors. Are the 2N5460 fets critical for low phase noise or are MPF-102, 2N3819, 2N5457, 2N5484, 2N5486 useable for low phase noise? The reason I ask is because this site: http://www.danssmallpartsandkits.net/ has them real cheap. Have you measured the phase noise since ARRL can't or perhaps too busy?
tnx

Jeez, you're not kidding. That's outrageous. They may have just drawn
what the author submitted, though, so I'm not sure if it's the
draftsman's fault.

1815. Re: development of the "Desert Ratt" regenerative receiver design

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-08-17 06:46:27 UTC
From: The Eternal Squire <eternalsquire@comcast.net>
Message-ID: <AoSdnTjRe41cNLzcRVn-pA@comcast.com>
Source record: 23947

Dear Mr. Moriarity,

Well, I finally used to scope to prove to myself
that I wired the phase splitter correctly.

I placed 100 mV p-p 1000 hz sine signal into C15. I get
proper 100 mv p-p 1000 hz sine signals that are
180 out of phase into pins 2 and 3 of U1.

R12 seems to be misspecified as well. On the
pdf schematic, R12 shows as "10W". I assumed
at the time that the W was simply a misconverted
omega symbol, so I had soldered in a 10 Ohm
resistor there.

U1 does not amplify at all!!! So, I figured
that perhaps it was a mis-typed "K". So I tried
a 10 K resistor.

With a 10K resistor as R12, I got a VERY nice
volume that filled the entire room. The only bad
news is that when I remove the input signal, I get
about 400 hz motorboating.

I wired a pot in place of R12, and found that the
threshold resistance was somewhat below 800 Ohms.
Much less than that, and U1 did not amplify. But
any value needed for U1 to amplify caused at least
a few hz of motorboating.

Please keep in mind that I am using ground plane
construction and that both leads and traces are
reasonably short.

Also keep in mind that I constructed only the
phase splitter and audio amp stages. Basically,
everything between C15 and the speaker, along with
the necessary D1/LED1/R4 voltage regulator.

My remaining hypothesis is this: Is it that I have
too much gain in U1? Should
I change the value of the capacitor, C18,
between pins 1 and 8 of U1 to adjust the maximum
gain in the hopes this will kill the motorboating?

I don't know how else to solve the motorboating
problem, especially in a circuit that NA5N billed

as inherently resistant to motorboating according
to the explanation sheet.

Again,

The Eternal Squire

Any resistor will do, as long as it can dissipate 10 watts!
Did you try with a 10W resitor?
I used a 25W one and it works perfectly ;)

Nonsense aside, I just dropped a line to Paul Harden at the VLA -
which btw is pro'lly the biggest RF-receiving system on this planet.
I hope he will find some time off his VLA retrofitting project to
visit here and clarify.

I made a few changes to the History file at
http://webfools.net/filippo/desert-ratt.html
adding a later version of Charles Kitchin's beginner oriented receiver
- one with a still lower part count, the result of a few month's
experimenting.

Also, a related matter:

Charles Kitchin mentioned that his bipolar designs for beginners have
become extremely popular, although his JFET ones perform much better.

a) Did anyone try the circuits proposed in Charles Kitchin's article
on "High Performance Regenerative Receiver Design"?

b) How does it compare to this
http://www.electronics-tutorials.com/receivers/regen-radio-receiver.htm
and to the DR?

c) Is the article still available? Is there a link I should add to the
DR history?

Not so much your GP FETs, but power MOSFETs, certainly. They do tend
to go 'pop' quite spectacularly.

You want a CLEAN oscillator for UHF and Microwave, use the Butler from Stephensen in QEX Nov/Dec 1999.Current limited and works every time. I use a half dozen in the shop as per original, and a slightly modified 5 volt version is in the N2PK VNA at 150 MHz. THAT'S a low noise oscillator!

Although I knew how crowbar protection worked on PSUs I was shown in a
dramatic way when I used a bench PSU to charge a car battery, for what
ever reason the crowbar operated and put a short across the battery,
lots of bright white wire and smoke for a few seconds.
A colleague of mine was a vehicle radio fitter and always wore metal
watch straps, until the day one bridged a battery supply and chassis. He
always wears a leather strap now and takes his watch off before working.

Back in the 60's I recall being at a party where everyone had too much to drink and some YL's car would not start. The 'guys' went out to help and checked the battery water level. The guy doing the checking could not see as it was dark and asked for light. He was talking about a flashlight and a helping hand showed up with a Zippo lighter. The battery exploded! Very lucky none were killed or blinded.

Hello to all,

As I approach senility I keep on having problems like the following:

I notice on the Desert Rat PDF file, DR2, that a short note states that the coil should be wound around the PCB. I have never heard of doing this before but it hardly matters as I had planned on building this circuit on perfboard or Manhatten style, and using my usual pill bottle as the coil form.

But now I am curious. Is there a board available for this project? I would like to know this method of winding a coil on a PCB as it might come in handy for a future project.

Or, have I just made an idiot of myself for misunderstanding how this simple coil should be wound? I am sure I will have many who will be glad to point this out to me.

73 and good wishes to all de WA2AFD

Me too, and the frightening thing is that I'm still working every day and driving on the highway! BTW, don't those pill bottles make wonderful coil forms? Nice high Q. Good for storing small hardware, transistors, all the stuff we used to use baby food jars for in the old days. And, the supply seems to increase every day, just like wire coat hangers. You have to do SOMETHING with 'em or they'll take over!

So you did. I have had troubles with the Butler many times when using both tubes and bipolars. Stephensen explained to me why, and I've never built one of his that didn't work as planned right out of the chute. PSpice may have helped, but the bipolar/FET was a great advance. I don't quite go back to spark, but am getting pretty long in the tooth as well.

Yes, I did see that. Rosin flux in orbit around the solder !

Did you also notice that they were using a Weller TCP series iron (50 year
old Magnistat design).
Quite a few good reasons for choosing this specific model for space
station - KIS - easy to repair - virtually foolproof -
needs only 24 volt (or 12 volt) bus to operate .. with no need for base unit
with electronics.

Ten ohms is the "right" value, looking at a LM386
data sheet.

> U1 does not amplify at all!!!

The LM386 should have plenty of gain if wired
correctly with these values. Something is very
wrong!

I am also suspicious of the connection of pin 7
on the LM386. I would disconnect it from the
junction of R12 and Cwhateveritis, and separately
bypass it to ground with a 10 microfarad cap
(plus side to pin 7). You might even get away
with not connecting pin 7 at all!

You should see a 440 RMS working volt 50,000 Joule MOV on a 600 amp
440 line that has received an over voltage spike.

The only thing left are the connecting wires and they are pointed
straight out. They are blinding if you happen to be looking at one
when it blows, or deafening if you are near. They'd put any 12 gauge
shotgun to shame.

These things are about 3 X 4 inches and just shy of an inch thick.
Used across a pair of 1200 VAC 1200A (as I recall) SCRs (Thyristors)

Hi, "John"!

I looked up an LM386 data sheet from National.
I also consulted your advice.

It turns out that the best solution is to
strike C18 and R12 completely, and to change
C20 to 10 microfarad.

Looking at the original schematic, it makes a
lot of sense... if you're trying to amplify
100 millivolt p-p of audio into 1 V (1000 millivolt)
p-p of audio, we clearly only need a factor
of 10 amplification, a.k.a. 20 decibel.

This is best accomplished simply by leaving
the connection between pins 1 and 8 open,
which by the way programs the LM386 for
its default 20 decibel amplification.

I found that R12 between pin 5 and pin 7 simply
provided a greater chance of a ground loop, so
eliminating that provided less chance of
motorboating even at 20 decibel amplification.

Then I took your advice to simply bypass
pin 7 to ground with a 10 microfarad capacitor.
This was easily enough done by changing
C10 from .1 microfarad to 10 microfarad.

With 100 millivolt p-p coming into the phase
splitter, the scope reads a clipped sine wave
at several volts... meaning that I have plenty
of gain to spare, I should even crank down the
input a little.

Because of the LM386 is amplifying a differential
signal, our effective amplification is actually
a factor of 20... so it would seem that nominal
input signal is actually 50 millivolt.

So, I believe that I have a working version of
that section of the circuit. I think I will
work on the detector portion (Q3) next, and
try injecting a 20 millivolt rf carrier at
14 Mhz.

I'll be back in a couple days with the results.

The Eternal Squire

<< I notice on the Desert Rat PDF file, DR2, that a short note states
that the coil should be wound around the PCB. >>

Howard-

There may be a misunderstanding. I didn't see the note, but had the impression
the coil was to be wound on a 35mm film cannister.

Looking at the other references, there were a couple of alternate plastic coil
forms suggested, with differing numbers of turns depending on diameter.

<< With a 10K resistor as R12, I got a VERY nice
volume that filled the entire room. The only bad
news is that when I remove the input signal, I get
about 400 hz motorboating. >>

Squire-

I believe R12 should be ten ohms. It provides a load at higher frequencies where the speaker or headphone impedance might be too high for stability.

The motorboating is most likely feedback via the power supply line. Therefore, the ten ohm series resistor should be higher (perhaps 100 ohms?), and the filter capacitor at the IC's power terminal could be increased.

The best references for RF transistor amplifier design are the Application Notes and Books by Helge Granberg, K7ES (sk). Helge worked at Motorola and passed away at age 63 in 1996. His Motorola application notes (AN762, AN749, AN758, AR164, AR347, AR511 etc.) include the theory, schematics and PC board layouts for construction of several different designs. Motorola use to publish all of Helge's Application Notes, but I have not seen these on the Motorola web site recently. Some of these Helge's Application Notes and Motorola Engineering Bulletins are available here:
http://www.communication-concepts.com/application_notes.htm

Many of Helge's designs (PC boards) and hard to find parts are available from Communication Concepts
http://www.communication-concepts.com/

He co-authored a book "RADIO FREQUENCY TRANSISTORS Principles and Practical Applications 2nd edition • 290 pages" with
Norman Dye. This book is available from RF Parts (www.rfparts.com) and
other book dealers. RF Parts also routinely handles international shipping.

http://www.fetchbook.info/search_Helge_Granberg/searchBy_Author.html

Some HF kits (RF Electronics -Lee Martin, KD4YBC) are also available for export
http://users.aol.com/rfelectron/rfelect.htm

http://www.qsl.net/gm0uhc/page6.html

Mike Grierson, G3TSO designed a 140W RF amplifier that appeared in January 1992 issue of RadCom (contact them for a back issue)
His web site does have photos.
http://www.qsl.net/g3tso/HFLinearFrameSet1.html

http://www.qsl.net/g3tso/images/Schematics/sshflin.pdf

JA0TJU is an excellent resource and reference for "broadcast style" RF amplifier construction
http://www.ginzado.ne.jp/~hamradio/tju/2c3286.htm

Pieter Ibelings, N4IP has a web site for construction and references Helge Granberg and Joel F. Paladino, N6AMG (sk) work in QEX ad QST.
http://www.ibelings.com/n4ip/mrf157.html

Dave Powis,
http://www.qsl.net/dl4mup/UKW45/UKW45_w.pdf

This should get you started on some research. Building is 90% reading, planning & design !

Mid-'80's ICOM R71A for sale. Recently removed from sailboat as I am looking for RX/TX capability and this SSB is RX only. It works. It shows no outward signs of any abuse. It comes with owner's manual and some schematics. No AC power cord.

Since anyone interested in such a machine knows its value, I'll ask that you simply make me an offer that will satisfy both of us.

Works well with plastic 35mm film cans as well...
Carefully drill a hole in the top the size of your coax - snug fit. If its
one of those fancy adult-proof tops, this may not be good. Go to a film can.

Cut a slit from the hole to the edge, with the trusty ole' Exacto knife.

Slip coax into hole via slit, connector towards indside of top.

Pull coax so connector is up against top.

Snap cover onto container.

Hopefully this is useful in some way...

==========

Well, it will have to do. Thanks Paul!

For the last one or two years of my varied career I was listed in the firm's phone directory as "Chief Standards Engineer". I had under some sort of control the Quality Managers of 3 factories and laboratories.

Strictly speaking, "Quality" is defined as the ability to conform to specified requirements. It can be statistically measured as can anybody's performance.

But in my case I would prefer the more lax and broader definition of Quality : The ability to serve the intended purpose.

"Reliability" is defined as Quality versus Time.

My programs, produced in retirement for a variety of reasons and purposes, have now been available to the 'rabble' for 5 or 6 years. ;o)

Here I go again - pouring out my heart with the aid of a bottle of Valencia red. It's supposed to be good for the arteries. It didn't do Franco any harm. But a pity about Guenica as depicted by Pablo Picasso. He should have done Nagosaki (which I witnessed from the air) and Hiroshima (which I visited on foot). Unfortunately my camera had a pin-hole in the bellows but the experience, nevertheless, profoundly influenced, you could say biassed, my early education.

1847. Texas Balloon Launch Team (BLT) to fly ham radio and GPS this saturday 10am

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-08-19 00:38:48 UTC
From: Craig Davidson <nospam@earthlink.com>
Message-ID: <sESUc.27239$9Y6.24209@newsread1.news.pas.earthlink.net>
Source record: 23979
Cross-posted to: rec.radio.scanner,rec.radio.shortwave,rec.radio.amateur.space,rec.radio.amateur.homebrew,rec.radio.amateur.equipment,rec.radio.amateur.digital.misc

It's time again for the Texas Balloon Launch Team (BLT) to fly their 20th
mission.

The Primary GPS APRS transmitter is on 440.950 Mhz FM

The Backup GPS system transmits on: 445.925 MHz FM

There is also a Crossband voice Repeater on the balloon which
transmits on 446.000 MHz FM

In addition there will be a Live television Camera transmitting its signal
on
1255 MHz FM

The balloon will take about one hour to rise to 100,000 feet where the
balloon explodes and the electronics payload parachutes back to earth for
another hour. You should be able to hear the balloon transmitting from over
300 miles away.

They will launch from the same airport in Wharton Texas
(http://www.airnav.com/airport/5R5) on Saturday morning at 10am and will
use most of the same equipment as BLT 19 last year. If the frequencies or
launch site change then I will post another message by Saturday morning.
The airnav web page shown above has a handy distance calculator where you
can enter the code for your local airport and it will tell you the distance
from wharton.

The GPS coordinates transmitted from the balloon are used to locate the
landing site.

The electronics package is also fitted with a Piezoelectric beeper to help
the recovery
crew find the payload in "that last 100 feet of tall grass".

See the photos from previous missions at:
http://www.qsl.net/w5acm/b18_1825.html
http://www.qsl.net/w5acm/b18_1826.html
http://www.qsl.net/w5acm/b18_1827.html
http://www.qsl.net/w5acm/b19.html

For all the non hams out there:

The GPS data is transmitted in APRS format.

To learn more about APRS click here:
http://www.tapr.org/tapr/html/sigf.html
http://web.usna.navy.mil/~bruninga/aprs.html

Receivers are available from Ham radio stores such as Amateur Electronic Supply http://www.aesham.com/ or Ham Radio Outlet http://www.hamradio.com/ Or you could look on Ebay for a 440 MHz FM receiver. You can also get a police scanner from Radio Shack to do the job. Make sure it receives the proper frequency.

You also need an antenna. I recommend the arrow antenna to get started:

http://www.arrowantennas.com/146-437.html

You will also need a packet modem to decode the APRS audio tones. The Kantronics KPC3 is an example http://www.kantronics.com/kpc3+.htm These units plug into the speaker jack of the receiver and also to the RS232 serial port of your computer.

Or you could try to decode the audio tones with software and your sound card instead of buying the modem above. Check out these web sites for packet software:

http://www.qsl.net/soundcardpacket/
http://packetradio.com/rascalmkv.htm
http://www.elcom.gr/sv2agw/agwsc.htm

Fred,

Maybe R12 needs to shunt the speaker to ground, rather than the
output of U1. If R12 is needed just for AC response, then it doesn't
make sense for it to conduct the DC between pins 5 and 7. By
shunting the speaker it should force the speaker impedance closer
to 10 ohms. I'll try that.

The Eternal Squire

1855. Norcal 38 Special Info needed

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-08-19 07:51:23 UTC
From: null1969@yahoo.com
Message-ID: <479c2105.0408182351.56627c08@posting.google.com>
Source record: 23987

Hello,
I am studying the Norcal 38 special design so that I can gather the parts and assemble one. I have extensively read the documents in the amqrp site. However several questions remain before I proceed. Surprisingly there is very little additional information on the web or google newsgroup. Can someone please post replies to my questions?

1. The schematic for the 5W mods & a RIT. The amqrp website give mods for the mods but not the original mods itself.
2. I will probably build the rig "ugly" style but a PCB reference would be worthwhile to study.
3. Has anyone tried "pulling" the oscillator to get more freq coverage? I believe the stock design has about 20kHz span.
4. Any other ideas since the 38 special was first released.
5. Use of NE612 instead of NE602. I think these are fully compatible with each other.
6. Design for increase the 12MHz IF filter to use 2 or 3 crystals. The manual says that the original PCB contains the provision but no more details.

Thanks in advance for replies.

Regards,
Jay

1858. ARRL Radio Designer

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-08-19 19:16:15 UTC
From: Joe LeKostaj <joe@falseaddress2004.net>
Message-ID: <joe-CF8262.14161319082004@news.covad.net>
Source record: 23990

Am looking for some basic RF design software that can run on an older PC laptop (Pentium II 266 MHz). I know ARRL doesn't sell Radio Designer anymore, but I'd be interested in getting a used copy of it or an equivalent that'll run on my older computer. Any suggestions? It'll be used just for hobby-level stuff, nothing very intensive.

Tnx & 73,
Joe K9LY

1859. Re: Measuring transitor impedances

Newsgroup: rec.radio.amateur.homebrew

From: bviel <sjouk@home.nl>
Message-ID: <cg3colpcv1@news3.tilbu1.nb.home.nl>
Source record: 23991

Yes, I did read the whole thread, how could a restate whitout reading the whole thread.
The "restate" is also the way a do measure S-parameters.
And I did say you need an angle also.
reflection coefficient = Vreflected/Vincident = polar magn. and angle
Whit angle I mean Phase Shift.
If you can measure polar magn. and angle, there is no need to go MUCH deeper.
The fact you did go much deeper is? Use of analog equipment.
The question was, instead of use VNA, use oscilloscoop?
Lissajous figures measurement method is very basic stuff, its stated in my scopes
manuel.
Work with complex numbers and Smith Chart is a hobby of me, so I know too what is a "complex load".
How to construct a direction coupler, stripline, any impedance, frequency, even a
direction coupler for every frequency if you only have to measure phase shift.
To measure the magn. I use the bridge of Wheatstone, with a zero biassed Schottky detector diode DVM and some formules.
To give 40,000 $ for a VNA is one way, do it with "things" around you with the
same results, Hey isn't that homebrew?
I don't think there is anything I can't measure, even noise density ! If it can't be
measured, I can calculate it.

Now the purpose for my reaction was, that you where going to think, hey dummy
HOW did you do it?
Instead of that you did reply, we where MUCH deeper....
That's the way (maybe a little unfair) I did reply, did I miss something?
I learnt that you should not trough your self away, someone else will do it for you !

BTW the scope is limited to 1Ghz, digital, full of wave calculations, anything you name.

Man... did you hurt me MUCH !

Would this be the end of this thread, a would not hurt anyone.
Maybe I should have not reply at all, I choose the wrong "entry".

My story may not be extremely spectacular, but I think it has a rather amusing moral...

I had for a number of years not bothered screwing down the top cover of my 13.8VDC 10A power supply, for whatever reason. Of course, every so often the top cover would move and expose the inside working of the supply, but that wasn't really a problem!(?)

Then one day, while doing my electronics trade course, we moved to the subject of AC safety and how not to fry yourself! Very interesting lesson and I scored 100% in the final exam for that subject.

Then I came home, rather pleased, reached down to switch off my power supply, and promptly shorted the 240V AC main switch with my finger! What was that about AC electrical safety again????

Another event, some years later, I was working on a tape deck on my workbench. I had to reach over the tape deck to get a screwdriver from the back of the bench, but of course I forgot it was still pluged in and promptly shorted the AC transformer inout with my forearm...

Luckily for me we had just installed earth leakage breakers and it didn't take long for it to trip... After that, whenever someone asked me "how long do these breakers take to cut out" I would always answer with "oh, about ARRRGG"

Cheers

Martin, VK2UMJ

I think the student version 8.5 of Serenade is basically the updated
version . The product that ARRL designer is made from was one of the
last versions of SuperCompact before the company became Ansoft.

This webpage has plenty of ideas.

http://www.rfengineer.cc/rftools.htm

Much more likely that it puts a fairly hefty current through the stuff between the electrodes on the business end. OK for passive components, wire, and jewelry stuff, but not necessarily so good for semiconductors.

Long time ago, pop mechanics ran an article
about making your own soldering iron by
using the carbon rod from a C cell battery
(carbon zinc cell)

The carbon heats up very fast and also cools fast
so no burns.

Not sure if this is spinoff or some other plastic/carbon tip.

Now, if they can sell them all, with little or no returns, they'll be in good shape. Stock is useless on a shelf. Ties up funds. Too bad I don't live there. Would be interesting to see how well they do.

They are essentially worthless (at $20, I couldn't resist the chance to try one). They are unable to put enough current through an object to heat it to solder-melting temperature, unless the object is very small and delicate (read: a solid-state component that would be easy to damage by using a soldering iron that deliberately passes current through the connection being made). It is tough to solder anything larger than or equal to the size of a 1/8-watt resistor lead with this iron, and you can forget doing antenna work or anything else that requires serious heat delivery.

It might have worked a bit better if they had dropped their series R and required lithium AA cells. As things stand, the miniature butane iron sold by Radio Shack at about the same price is a much better deal.

They have a three-minute QVC commercial for it. It's obvious that it's running current through the object to be soldered; they show the little red "power" light going on and off as they touch and un-touch a solder pad on a circuit board.

Like the Radio Shack butane unit, the device is $20 and tips are $10. They have three different tips shown. Takes 4 AA batteries.

"This tool is appropriate for most electrical projects with wires between 18-24 gauge, small jewelry repair, and electronic projects."

"We do not recommend it for soldering of large metallic components that require a lot of heat transfer, such as heavy gauge wire. Also be aware that high temperatures will be created during active soldering; please consult your component's datasheet for any special precautions needed."

"What is the spark I see sometimes during soldering?
"The spark (arc) is caused [sic] electrical current passes from one half of the tip to the other. Although the tool's spark should not damage any electrical or electronic components, we recommend caution when soldering sensitive components. Also, ensure that the tool is not used in flammable or explosive environments, such such as near gas or gasoline fumes."

One thought that occurs to me is that it looks like a DYNAMITE tool for desoldering with a suction device, since it appears that solder doesn't stick to the tip it ships with. Can't speak for the other tips; they look more metallic and are not demonstrated on the site. They recommend wick for desoldering, but those of us not of that religion might have an alternative.

Serenade is no longer available.

Ansoft does offer a free feature-limited "student" version of its
successor product "Ansoft Designer". I've heard that this student
version lacks some capabilities which were available in Serenade. I
haven't tried it out myself.

Good info Clif...Bill, whatever,
Boy, you new guys sure don't know what's been around for a long
time...(:-)
OLD idea. LOW voltage, HIGH current.

It is called "resistance soldering". I believe it is most important to
know that the current is only passed through ONE of the pieces being
soldered, not through the joint being soldered. In the QVC video, notice
that he only does one piece of wire and what look like solder blobs on a
board....

In fact, this is how soldering *GUNS* work! The gun "TIP" is a 'wire' &
has a high current from a transformer secondary that is in the gun body.
Long ago I stopped buying soldering gun tips and just use #12 or #14 solid
copper wire. Sometimes in really weird shapes to unsolder IC and the like.
It is interesting to see what the strong magnetic field around the tip does
to molten solder... Reminds me of that recent NASA video about the solder
flux in space...
The (soldering gun) secondary is 1 or 2 turns for fractions of a volt at
MANY amps. I should measure it, but I think it CAN NOT damage a transistor
since it is less than 0.4 volts (I think, far less)
I have a professional resistance soldering unit used for making dental
braces and similar things and it is powerful enough to do PL259s _VERY_
well. Heavy wire to the probe and large clamp and several secondary taps.
Interesting thing is that the manufacturer uses the blue handles from
Weller, so it looks like a Weller soldering iron, but with an extreemly worn
and oxidized tip, since it is not tinned. Looks carbon-like.

More info I found with a quick Google:

FOLLOW-UP...

The "Explanation" text I refer to below says that you put current THROUGH the joint you are soldering. This can be done, but be careful. He expains the effects of resistance in the joint.

Remember in ALL soldering, the goal is to heat the _JOINT_ and let it melt the solder. [[but it is _very_ helpful to use a small blob of molten solder to get a good heat transfer to the 'work".

The idea is to get in and get out without heating surrounding stuff any more than necessary (including the solderer tips themselves)

Arcing is caused by INDUCTANCE. As Newton once said, "Inductanace abhores a current change." [[much like Voltare once said: "Capacitance abhores a voltage change.]]

When current flows in an inductance, the inductance will do "whatever it takes" with the voltage across the inductor to keep the current constant -- including generating a *VERY* LARGE voltage in order to create a low resistance arc (so to speak), when we foolishly try to interrupt the circuit. This is how engine spark coils woik)

High school.
My buddy Pete has one of those continuous AC electrical outlets on the side of his desk. You know. Two continuous brass strips in a foot long plastic housing with two slots, into which you shove the (older two bladed) plug.

Well, one day he needed some line cord, which he ALSO had hanging on the peg-board on the side of his desk
SO... He reaches around the end...grabs some line cord and proceeds to cut off a piece with scissors...

Blam! ... notched scissors!

Outlet strip had the same kind of brown, two conductor cord.

I knew that. :) Seriously, to me the big celebration here is the material that allows you to make a low-resistance connection to the work every time.

We used to have fun with a low-voltage, high-current power supply that some wag labeled "Zotz I" (but everyone mistook the markings and called it "zotsy"). It was the (fairly) early days of tantalum caps, and we'd hang Zotzi across the power supply rails to find shorts by heat. On occasion we'd launch a smelly and formerly shorted tantalum that way.

On a vaguely similar line my father was rewiring an outside building and
carefully removed all the fuses from the fuse box before cutting out all
the old cabling. He then came across a cable he had forgotten and cut
this too, BANG!! It was the input to the fuse box. One very badly melted
pair of cutters and a rather startled father.

I gotta. I just gotta.

About 25 years back, I was a new systems programmer for a government agency which I'll cleverly call WeBuildHighways. Our sister shop, the Department of inHuman Services, was fairly close, and we spent a fair amount of time visiting and swapping hints and kinks.

One day I was there while some remodeling was being done: an old door wsa being blocked and a new one cut. I heard a Skilsaw fire up, saw a blade movingd ownward, and cringed: there was a quad-box about a foot below the blade and in its path.

My counterpar was a bit quicker, and shouted "Turn Off All Your Terminals RIGHT _NOW_!!" -- just before the blue flash and the great dark silence.

This was before PCs, and so we only lost some 3270 terminal sessions to the mainframe. It was ... interesting.

Another time I'll tell about The Guy Who Blew Himself Through The Door.

Inductance doesn't magnify current. In fact, it's a fundamental property -- even a definition -- of inductance that it resists any change in current. And to do that, it can elevate the voltage by a whole lot. For example, if you have current flowing through a coil and break the connection, you commonly see a spark or arc (and can get a shock even with a low applied DC voltage). This is caused by the very large voltage the inductor produces in its effort to keep the current flowing through what has become an open circuit.

12 years back there was a CB'er that had a double 3-500 Z amp with 3500 volts on the plate that lived next door to me.

One day he noticed he was running about half power instead of full bore so he popped the top of the amp and noticed one of the wires on the tube caps (PLATE) had come unsoldered.....so instead of turning the amp off he melted the solder a bit with his insulated soldering iron and forced the wire back into the molten puddle....It worked!.......Then holding a large roll of bare solder in his hand he added a bit more to the molten solder

It didnt take him long to let go of that roll of solder in his bare hand!!!

His entire hand was burnt white!

I have an ADI built Radio Shack HTX-204 dual bander, and need to get parts for it. It's the same, well almost exactly the same, as the ADI-600 I believe.

I have done web searches, and with the exception of dealer links, they only come up with ADI-radio.com as the manufacturer link, but that takes me to some generic search page, not ADI.

I need a valid ADI (manufacturer) web address, email address, and/or their mailing address and phone numbers if someone has them please.

Thanks in advance for your help.

Something similar happened to a friend who was doing some soldering on a power amp that was still switched on. He wasn't as stupid as that CBer above, oh no. He had passed his amateur exams, so he knew he was working on a "safe" part of the amp, well away from the 3kV.

Well...

He was using a whole reel of solder, and holding the end between finger and thumb, kinda like you do. But he wasn't paying too much attention to the rest of the reel - it slipped off his other finger, and unwound into the amp. Guess where?

He had a nasty little burn on his thumb, and an even nastier little hole in his shirt-front where his chest had been pressed against the case of the amp. He's very lucky indeed to be alive.

I use the A/D system in a PIC microcontroller.
The most simple is the PIC16F684.
It actually has an on chip crystal
oscilator in a 14 pin dip so parts count
is at a minimum.

I use a passive resistive network to
extend the range. Input is thru a
10K pot connecrted to ground thru a 1K resistor.

Input to the PIC is at the junction. Expecting
a 30 volt input I set the pot to 5K and then
multiple the result by 6 in the PIC. You most certainly should
use an appropriate 30 volt Zener to limit the raw input. There are
literally software examples by the thousands for PIC
micros on the web. You should be able to very easily roll your
own software for any application. MicroChip (PIC maker)
even supplies a free suite of assembly programs. Look
for "IPROG" as your programming software. My programmer
for the PIC is so simple you can make it on the
back of a DB25 IDC connection. Everything you need to
know is out there.

Co-worker of mine wore his nice shiny new anniversary wrist watch
(with metal band) while working around his car battery. Pushed his
hand down into a tight spot and shorted the hot terminal to ground
with the band.

He said there was a flash and suddenly the band was starting to glow.
He jerked his hand out almost instantaneously, and the watch and band
sailed across the garage, hit the wall, and crashed to the concrete
floor.

He wore a bandage around his wrist for a couple of weeks, but all he
has to show for it now is the brand around his wrist that the
watchband left behind.

I have no idea what he told his wife....

Hi Group,

Picked up a few good Direct TV disks around the local area. The LNA on them says 12.8GHz.

Can anyone point me to a site or give me some general infomation on this things? I would assume that the cable between the receiver and LNA also supply the DC voltage.

Is there any other band I could use the disk for? How about using it for the 2.4GHz or 5.8GHz band where there are video link equipment avaliable.

Tnx de KJ4UO

if you go to this site

http://qrp.pops.net/qrp/default.htm

and look at the

http://www.qrp.pops.net/cascoder1.htm

its designed for 7 MHz but you can change that by downloading

http://www.qrp.pops.net/apps/resonator.zip

and putting in the frequency of your choice, the schematic it will give you,
should be enough to change the front end of the 7 MHz RX..
That should get you 1/2 way there..

GDMs are useless for anything above HF. There are plenty of circuits
around that will cover up to UHF, but they're hopelessly clumsy to use
in practice at such frequencies.

Just a suggestion, but if you want to save some time on the project
and still do it dirt cheap: check out eBay auctions for grid dippers,
and watch for high quality units (early Millen, etc.) that are missing
the coil sets. They usually go dirt cheap. Since you'd have to
make your own set of coils for a homebrew, might as well
consider making them for a good quality commercial unit. I'm kind
of partial to the Millen.

Gad... Why bother? The analog channels that a scanner can deal
with don't have a lot of traffic on them, and there have got to be far
more interesting listening experiences Out There.

If you're bound and determined to bore yourself to death, the
Realistic PRO-2004 is easily modified to cover the analog cell channels.
You can probably find one on EvilBay with minimal effort.

Happy hunting.

Depending on what you want to do, you might try RFSIMM99 which is a fairly powerful S parameter simulator program.

It is free and if you do a search for that name you ought to get a lot of sites to download it from.

==========

When I set the passive components to use real world models, I can enter the self resonant frequencies and so on from the catalog for the particular component I want to use.

Then, running Random Simulation mode, I can find if my design has critical components. I like that !!!

The ability to include real world parasitics is a nice part of the program, and I use it to keep my designs as tolerant of the actual components as possible.

> something like that and forget to take your watch off or whatever.

Paul; I guess mine concerns 'zero amps'. Particularly, a motor generator unit comprising a 48 volt 200 amp DC generator driven by a shaft coupled 3 phase 230 volt motor, which we moved a few miles. After supervising the move, at night, I left the in charge technician and the crew to finish off and went home to bed. Around 01.30h, I was roused by a phone call, "No output". This unit HAD to be working by 09.30h at latest, next morning! During the move the DC generator must have lost its 'residual magnetism' and when restarted was putting out +9 volts instead of -48 volts and consistently tripping the output circuit breaker when they tried to connect it to the working equipment and batteries!
Although I had never encountered it before I had sufficient technical background to surmise what had happened and after blowing a few fuses and burning off a temporary lead in my hand was able to get sufficient negative 48 volt voltage onto the field winding of the unit. It recovered and was there until all the equipment in that building was retired some 15-20 years later.
Phew!
PS. 200 amps @ 48 volts is some 10 kilowatts, the output of one motor generator set and there were 3 of them.

1931. Farhan's Final

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-08-23 07:09:55 UTC
From: meara.london@virgin.net
Message-ID: <22f6e3ee.0408222309.f99f51c@posting.google.com>
Source record: 23813

I've been looking at Farhan's very FB SSB Transceiver
http://farhan.net.co.nr/xcvr1.html

I'm trying to understand the biasing on his IRF510 final, and the RF output he's getting.

He says he measures 20-24 volts peak RF across a 50 ohm load at the output. That's about 8 watts peak output.

He's using 12 volt supply, and recommends setting the idle current through the MOSFET at 80 ma. Can that be right? According to my reading of Solid State Design for the Radio Amateur (SSDRA)(page 23) with a 12 volt supply we can expect peak signal voltage at the Drain of around 12 volts (with an RF choke in Vcc line). Peak current could be max 80 ma.(maintaining Class A). Under these biasing conditions, assuming Class A operation, max output power of .96 watts would be provided by a load of 150 ohms.

I'm very new to this kind of analysis, and strongly suspect that I'm misreading either SSDRA or Farhan's excellent article.

Can someone please let me know where this apparent discrepency is coming from.

Thanks and 73

I heard of a newly installed phone exchange generator that kept stalling when they cut it on to the load: they pulled it all apart and checked every part of the alternator and diesel motor with no success.

Then one day they were trying again and these linesmen rushed in from the pub next door shouting and screaming: The grid in the area had been shut down for line repairs so the immediate city block had no electricity. They were knocking back a few coldies when they heard the roar of the generator and saw the lights in the pub flickering.

It seems the techs had wired it in without relays to isolate the line input cables and were trying to power an entire city block: no wonder it was stalling. They were lucky they didn't fry a linesman too.

There is a lot to be said for nipping in to a pub occasionally. Maybe one could find a lot of safe linemen there.

This kit is sold out as of 8/19.

From the site:

" LF Converter kit - sold out (8/19/2004)

Please email: jacksonharbor @ att.net
if you would like this kit revived."

I hope he gets enough emails to reinstate it.

Hey fellow hams. Just found this newsgroup, been inactive for about 22 years but find that it's a bug bite that won't go away, especially now with the kids getting old enough to appreciate their dad's weird habits huddled over a workbench. Homebrew is what ham radio is all about - built my first transmitter on a piece of wood using finishing nails as tie points. (Anybody remember the Electronics Illustrated cover article describing same, circa 1970?)

Anyway, back to my subject, I'm looking for a surplus 19" equipment rack. The net has tons available but, obviously, no point in spending $100 to ship something worth no more than that.

I'd appreciate any guidance on this.

1940. Trimmer capacitor queries

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-08-24 08:12:16 UTC
From: Richard Sterry <no_spam@all.ever>
Message-ID: <cget96$8su$1$830fa7a5@news.demon.co.uk>
Source record: 23822

Hello all.

I have a few small air-spaced variable 'trimmer' capacitors, obtained some years ago for a project (one of many) which never got off the ground. They are in excellent condition, apart from the inevitable silver tarnish. I thought I might eBay them, but first there are some things I need to find out.

It may seem a daft question, but are the plastic dust jackets merely to protect them until they are installed on a PCB, or are they intended to remain on afterwards? The access hole for the trimmer screw seems to suggest the latter, whilst the fact that the two halves are held together with adhesive tape seems to suggest the former.

You can see a photo here - http://tinyurl.com/6qr7m .

My next task is to identify the value of the two types that I have, one with 5 movable vanes and one with 7. They are identified on the adhesive tape as TL 10 followed by 24/3 and 24/4 respectively, which doesn't tell me a fat lot. The problem with Googling is you can have simply too much information, and this is the case here, so I need to narrow down my search in order to make any progress. Does anyone have any idea where I should be looking?

Failing that, I'll have to blow the dust off the old GDO (it really does have a grid and not a gate!), fish out some VHF coils and some fixed capacitors, and do it the hard way!

You don't need to establish the value to sell 'em, although it may
help. But the kind of people who will go for this item are probably
not that bothered. They could easily be 24pF., but it's hard to tell
without any scale to the picture.

I have since learned that these are for protection from solder splashes etc.
during assembly, and are removed afterwards.

I like to provide as much info as possible. There are two different sizes,
one with 5 movable vanes and one with 7, and as the size and spacing of the
vanes is the same I would expect their capacitances to be different - unless
I'm missing something, which is perfectly possible!

The fixed capacitors are for calibration purposes, the values of the
inductors being unknown (just airpspaced coils). BTW, the GDO is a Heathkit
GD-1U - heavy, mains powered, but works a treat!

1943. Vertical Antennae matching

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-08-24 17:46:33 UTC
From: "Airy R. Bean" <me@privacy.net>
Message-ID: <2p1dcjFfvldbU1@uni-berlin.de>
Source record: 23825

It seems to me that if I have a vertical antenna with the ATU at the base of it with coax back to the shack, that all I need is a series inductor to tune it for frequencies for which it is shorter than 1/4 wave and a series capacitor for frequencies for which it is longer than 1/4 wave.

What do I do, however, for those frequencies for which it is close to a half wave? PI network? Or L network?

1944. Re: Vertical Antennae matching

Source record: 23826

> What do I do, however, for those frequencies for which it is close
> to a half wave? PI network? Or L network?
>
==========

You very slightly de-tune (decrease) the antenna length, not enough to have any effect on its radiating properties, such that a simple parallel tuned matching circuit will cope.

You can connect a coax feedline line either in series with the coil, an L-network. or tap the coax a few turns up the coil. A very modest ground connection adjacent to the bottom end of the coil witll suffice.

The same circuit will cater efficiently for quite a wide range of antenna heights.

I hope you are satisfied with the above description.

From: TIFort <beerbarrelNOSPAM@cox.net>
Message-ID: <rf7ni05eq23b28vg3lu1v2mgl3dbch7kqa@4ax.com>
Source record: 23827

Does anyone have an idea what a suitable replacement would be for a MPF102 transistor? The MPF102 comes in a TO92 case. I would like to find a transistor that would sub with this but be in a surface mount package. I've looked at quite a few places around the internet but can't get one to cross exactly. If it's not a exact match, I guess I could go with one with a little more gain.

Thanks,
Tracy

Source record: 23829

While not low voltage, I remember reading in the '60s in Scientific American an article which mentioned how many milliamps of current was enough to be felt / dangerous / deadly, etc. It mentioned that substantially larger currents could sometimes even be safer as they could cause involuntary muscle contractions which would interrupt the current flow.

The example given was of a worker at a high-rise construction site in New York who was changing out of his work clothes at the end of his shift in a temporary shack that also housed the site electrical power connections. While doffing his trousers he accidentally backed into a high voltage panel. An estimated 60 amperes passed from one buttock to the other through muscles that immediately straightened, propelling him through the shack and its door and into two lanes of road traffic which immediately stopped.

Because the current didn't pass through any vital organs, he only sustained surface burns and various bruises and scrapes though the electrical panel manufacturer's logo is now mirror-image tattooed to his behind.

I've *gotta* find the source of all this...

60 amps though "Human flesh" will cook it well done! 15mA through the vital organs will kill! As little as 30 microamps will cause a severe muscle reaction and not even the sturdiest will be able to resist movement if the current reaches 2 mA.

It's not that simple. Getting the antenna resonent is one issue, getting it matched for 50 ohm coax is the other issue. So a simple inductor or capacitor won't always work by itself. Helps with resonence, but not impedance.

1952. Re: Vertical Antennae matching

Newsgroup: rec.radio.amateur.homebrew

Please forward this to your friends!

We are looking for contestants to star in a new reality TV show called Final Table Challenge.

The show is scheduled to run like a live Poker TV Show with our first Show at Sams Town in Las Vegas.

The lucky winner will then compete against other poker players in a chance to win some cash and become a TV celebrity.

The worst that will happen is that you get a trip to Las Vegas and you play some poker on our dime.

You should be up for a great time.
Looks etc are not important, but you must be ready for anything.

If you think that you and / or your friends have got what it takes to make it onto the show, just visit our registration and sign up.

http://www.finaltablechallenge.com/registration.php

To find out more details and how to apply to be on The Final Table Challenge TV Show please visit our web site.

http://www.finaltablechallenge.com/registration.php

The signup is free and takes less than 30 seconds. Remember, you can't win unless you're in so apply now !

Don't forget, we want to hear from your friends too, so please forward this mail to them all.

1956. Re: Vertical Antennae matching

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-08-25 16:49:39 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <10ipgp766lmgg49@corp.supernews.com>
Source record: 23837

A common solution is to use a parallel tuned circuit, approximately resonant, with inductor and capacitor reactances of a couple hundred ohms or so, and the capacitor being adjustable. Connect one end of the network to ground and the other to the antenna. Connect the feedline between ground and a tap near the bottom of the coil. Alternately adjust the tap position and the variable capacitor for the best impedance match.

I'm never satisfied, always driven by the spirit
of curiosity and discovery!

Changing the vertical length is not an option as its
an ally pole supporting a tv antenna; it just happens to be insulated
from the ground.

I was planning to put about 20 radials in green-and-yellow, splaying
out from a single copper stake.

Presumably the roller coaster could be used for
a vari-tap, but then that means that the whole coil
will always be in circuit.

Time for a quikc .XLS for all bands.....

Interestingly, I hardly ever use my grid-dipper anymore after building
the L/C Meter IIB from www.aade.com. Tank circuits at less than 50 MHz
or so can be set up by just measuring the component values in question
and running the numbers.

I don't have anything to do with the AADE people, just an unsolicited
testimonial. If your work is primarily at HF, you will find a high-
precision L/C meter just as valuable if not more so. (Of course, it
can't act as a signal source or an absorption wavemeter the way most
real GDOs can.)

There's no reason you can't make the inductor variable instead of the capacitor -- as long as it has some way of making a variable tap. With the method I described, you have to be able to adjust both the tank's resonant frequency and the tap in order to assure getting a match.

Generally true, Roger, but *time* is as important a variable as well. To cook anything well done takes substantial energy and that's a function of current, voltage and time. The point of the story was that the effect was immediate, the current flow brief, and the surface was still burned.

I don't volunteer to try recreating the experiment though!

Hi,

I bought a big bag of surplus assorted trimmer pots at a radio rally 2 years ago. They're all unused, which I assumed meant they'd be trouble-free. However, many of them seem to have gone very 'noisy' and if one tries to wind them from one end to the other, the resulting voltage readings jump around a lot and often have 'blank' areas for part of an arc where no contact seems to be being made between wiper and track. I immediately suspected that they'd probably require a good dousing with switch-lubricant, but I'm not sure if that's the best remedy and even if it is, there doesn't seem to be any serviceable access into them through which one might be able to spray some lube. The ones I have are between a quarter and one-half inch in diameter approx and have a protective casing around them, unlike the good old skeleton presets one could get at easily. Anyone care to give me any tips on the best way to revitalise these old pots?

Thanks.

No way if these are sealed. They are probably carbon composition, which is notorious for getting noisy with age. The trash container is where I would deposit them. New ones are not that expensive, but I have used new ones that are noisy.
Ham radio stuff, they might work after a fashion, but I would be very careful using them in a critical circuit.

Dual-gate MOSFETs like the BF981 are widely available in SM. You could tie
the two gates together. You will probably have to modify the circuit,
though.

I'd be curious what you hear. The 2790 series seemed to be pretty
similar to the 490 series, which is very well-documented. But the
contemporary 2782/2784 models weren't documented at all beyond the
module level.

Maybe Jim Yanik (ex-Tek service guy) will see your inquiry and respond.
You also might try the TekScopes reflector at Yahoo Groups.

A trimmer pot shouldn't be intended for use in a circuit requiring
frequent adjustment - which means that the noisy behavior you
see may not be a show stopper. You can crank the thing through
a few cycles which may clean it well enough for use. If you are
going to toss them anyway, then experiment to see if you can salvage
them. Someone mentioned WD-40. You could dunk one in
isopropyl alchohol and crank it while immersed, then let it air dry.
It's worth experimenting, even if you end up tossing them all.
At least you'll learn what doesn't work!

1976. QRP receivers: LM386 as audio filter + amplifier ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-08-26 08:44:07 UTC
From: n1jpr@hotmail.com
Message-ID: <95a201e0.0408260044.76f4b27c@posting.google.com>
Source record: 23758

I would like to build a minimalistic
AF chain for small HF receivers,
that would limit the audio passband
to either 300-2800 Hz or 700-900 Hz.

The LM386 audio amplifier has a tempting inverting input.
Did anyone try to design it into a 1-device
audio filter + power amplifier?

I looked around, pored over the applications sheet,
but found no examples.

I did this playing with TAA611's many years ago. Then I did find
rather clear indications on how to lower the high frequency cutoff -
but nothing similar with the LM386.

Any hints?

Or,
why isn't this done
as a matter of course,
as I
perhaps mistakenly
think it should?

In the old days (many years ago) we used "Quietrole", a red liquid,
on pots. It contained carbon tet AND a lubricant (I was told back then)
and it worked very well. Of course that was on the older rotary pots
in use at the time.
I think that stuff may still be available in a spray can, but it
has been quite a few years since I bought a can of it. --Phil

If you are going QRP there are now much lower ambient current devices than the LM386 -- secondly, if you go to Texas Instruments website you can download their FilterPro software -- you can program gain and Q into the devices. Analog Devices also has some good interactive filter design software.

Hi, Just get a can of tuner spray, sometimes called TV tuner spray,
tuner shower, etc..
That usually works. It is a common thing.
Most of the electronic stores will have it.

DeOxit makes a 5% spray that's good. However, the OP says he can't see a
way into the trimmer body.

1989. How to bias a MOSFET amp?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-08-27 05:40:36 UTC
From: meara.london@virgin.net
Message-ID: <22f6e3ee.0408262140.383c9581@posting.google.com>
Source record: 23770
Cross-posted to: rec.radio.amateur.homebrew,sci.electronics.basics,sci.electronics.design

I'm trying to improve my limited understanding of how RF amps operate. I've been studying "Solid State Design for the Radio Amateur" and Experimental Methods in RF Design"

SSDRA has a very helpful section that asks the reader to calculate max output power for a Class A RF amp (common emitter). They ask the reader to consider maximum voltage and current swings in the collector circuit that will keep the output linear. Basically, my understanding is that (with an RF choke in the Vcc line) max peak signal voltage on collector is Vc-Ve. Max peak current is the standing or quiescent current. In this way when the collector voltage is hitting its peak collector current is dropping almost to zero.

While the SSDRA example uses BJTs, I'm guessing that essentially the same restrictions would apply to the drain circuit of a MOSFET amp.

Here's my problem: When I look at MOSFET amp circuits in the literature, they often have linear amps with 12 volts on the drain, but with standing currents of only around 40 milliamps. And they claim 7 watts out. How can that be? Using the analysis outlined above, I'd think that you'd get max output of 12*.040 = .48 watts.

Here's an example: I've been looking at Farhan's very FB SSB Transceiver
http://farhan.net.co.nr/xcvr1.html

I'm trying to understand the biasing on his IRF510 final, and the RF output he's getting.

He says he measures 20-24 volts peak RF across a 50 ohm load at the output. That's about 8 watts peak output.

He's using 12 volt supply, and recommends setting the idle current through the MOSFET at 80 ma. Can that be right? According to my reading of Solid State Design for the Radio Amateur (SSDRA)(page 23) with a 12 volt supply we can expect peak signal voltage at the Drain of around 12 volts (with an RF choke in Vcc line). Peak current could be max 80 ma.(maintaining Class A). Under these biasing conditions, assuming Class A operation, max output power of .96 watts would be provided by a load of 150 ohms.

Even if he were to be running this amp Class B (or close to it), I can't see how he'd get 8 watts out with only 80 milliamps of standing current

I'm very new to this kind of analysis, and strongly suspect that I'm misreading either SSDRA or Farhan's excellent article.

Can someone please let me know where this apparent discrepency is coming from.

Thanks and 73

Keep studying.

The static bias is the zero-signal drain current and your calculation is for static DC loss. Signals applied to the gate can add to the drain current, as well as subtract.

RF final amps are unlikely to be biased classA. Class B and C will have the final acting more like a switch. Current is imited by the load impedance - which in this case is a complex impedance that looks like 50 ohms at the output only.

As to the answer for your posting - the fet in this case is biased by varying gate static voltage using the variable resistor in the schematic, as instructed.

It's a bias voltage, rather than a bias current. The MOSFET enters its
linear conducting area after a certain threshold voltage is attained.

With the Quietrole stuff and the old rotary pots, we used to have
some success with taking the knob off and dropping some liquid on the
shaft. It didn't work as well (as fast) as squirting it into the open
spot on the pots, but it would work many times.
But as I remember it, it was important to get something specifically
for cleaning pots, since carbon tet by itself would not leave behind
the appropriate lub for a lasting solution. --Phil

I think the RF guys (I'm not one!) call an amplifier "linear" if the RF output amplitude follows the input drive amplitude. You can do this with a transistor that has very low quiescent bias. So "linear" does not mean "class A" to them. The key here is that an RF amp has a tuned output, whereas an audio amp doesn't. So the lopsided bias would normally produce intolerable distortion in something like audio, but the tuned output circuit changes the pulsey-looking collector/drain current back into a nice sine wave. So you don't need a lot of idle current, and the transistor really amplifies half of the incoming sine cycle.

Most mosfets are pretty nicely linear (ie, straight-line Ic/Vd curve) beyond the initial knee. You could get gobs of watts at zero standing current, but then you'd have some zero-clipping (no output) for the smallest drive levels, so a little idle current helps.

That's a good point. Given that they will all divide the timebase down
to a very low frequency, even if there's nothing specific one could likely tap
higher up on the divider chain.

> Does one use ordinary masonry drills?

> Any undertakers out there?

A quick Google search on "drill marble slab" came up with hits to
support my first idea for drilling the marble: use a copper tube
the diameter of the hole you want, in a drill press at _low_ speed,
with lots of (fairly coarse) abrasive powder, lots of water, and low
pressure on the drill bit. It's the same rig I use for drilling glass.

You will want a stream of running water so that the bit is kept cool
and lubricated, and the abrasive doesn't turn into a hard paste.
It will be messy; if you can put the slab in a cookie tin or
aluminum-foil pan, and run the excess out through a tube, that will
help. You also could build a modeling-clay dam around the hole.

It's almost impossible to over-lubricate, but it's really easy to
under-lubricate.

See http://www.shopsmartxpress.com/AmeriGls/AmrDefault.htm?M9a.htm
for some useful tips.

Polishing is easy: coarse-to-fine sandpaper, then buff with increasingly
fine powdered abrasive, up through white rouge or so. You have to get
all the old abrasive out of the polishing tool before you put the new,
finer abrasive in -- but you knew that.

Marble is rather soft, though quite abrasive, and so it's easy to
take off more than is necessary.

If you are just going to drive the gate of the frequency counter, the gate is typically 1 s, 100 ms, 10 ms etc. so the 5/10 MHz reference frequency is divided down a few times anyway, so why do you need the 50:50 mark:space ratio ?

The frequency divider chain will change on either on the leading or trailing edge of the clock (but not on both), so the gate time will be 1.000000 s regardless of the mark/space ratio, provided that the clock mark/space ratio remains constant.

What looks like a very nice circuit is available at Harry's site.

http://w1.859.telia.com/~u85920178/use/gdo.htm

This site includes all the info you would need to contruct your own dip meter, including coil winding information.

Please forgive me if this has been noted before; this was the first site to come up on Google with the request of "Grid Dip Meter Circuit."

The only sensible way to do it AFAICS is to operate the MOSFET in
class C as a high speed switch and reconstruct the pulsed output into
a sine wave carrier by means of a suitable tuned circuit. I wouldn't
consider driving a MOSFET for RF use in any other way. The efficiency
should be pretty darned good, too.

That doesn't make any sense to me.

Unless things have changed pretty drastically from how they were when
I was doing RF, class "C" was pretty much relegated to FM, so that
when you hit PTT, you banged the hell out of the final and filtered
the hell out of the carrier, which went to maximum amplitude and
stayed there, and the information was put on the constant amplitude
carrier by varying its frequency (or phase).

AM and SSB finals were _always_ linear amps and, like John said, the
amplitude of the carrier/sideband(s) followed the amplitude of the
modulating audio precisely.

Whether you use a MOSFET as a switch or as a resistive element
yielding a linearly varying output depends on how you tailor the
characteristics of the MOSFET to fit the application. After all,

there are lots of linear audio amps out there with MOSFET class A and class B finals, aren't there? So why shouldn't there be linear MOSFET RF amps as well?

That means, to get a linear amp, the input signal has to be converted
to PWM gate drive. That's hard to do at high frequencies. At 300 MHz,
a power mosfet doesn't much look like a high-speed switch any more.

RF guys call the amplifier "linear" if the output, after filtering,
looks like a bigger version of the input -- basically the same criterion

as any other amplifier. The reason that you can get away with half as many active elements as with an audio amplifier is because if the modulation is narrow compared to the carrier each half of the waveform looks the same, so amplifying half of it then filtering reconstructs the half you didn't play with.

Class A amplifiers (and push-pull class AB or B amplifiers) are used in RF work, but mostly because they cut down on the harmonics that must be filtered out.

Well, AM tube finals were often operated class C with the modulation
applied to the plate supply. This is harder to do with silicon because
the varying collector voltage modulates the collector-base capacitance
and causes weird phase shifts.

And there are linear MOSFET RF amps; they're necessary for single-sideband.

Certainly not at that kind of frequency! But for the lower HF bands,
it's *perfectly* feasible.

Funny, I never considered plate modulation to be class C; that is if
we're talking about the same thing. What I'm thinking about is when
you key the transmitter on and it starts putting out a carrier at some
level, then you modulate the plate supply with audio so that at the
low peaks of the audio waveform the output of the TX is zero, but at
the output of the high peaks it's twice (?) what it was with no
modulation. Is that class C?

The balloon was successfully launched last Saturday. It reached 83,000 feet over Texas before the balloon burst and the electronics payload parachuted back to earth. Amateur radio operators were heard talking through the cross band repeater from Galveston, Houston, Dallas, Austin, and Rio Grande. Recovery was as simple as entering the last broadcast GPS coordinates as a waypoint into a hand held GPS receiver and following the arrow to the landing site. Conveniently the package landed only a few hundred feet from a paved road.

Watch for future balloon launch announcements at:

Have you actually built a class C linear RF power amp? Tell us how it
works.

It can be. Depends on the biasing. It *is* AM, however.

Class C just means that the conduction angle is less than 180 deg. I recall seeing it specified as a certain amount less than 180 once, but I don't recall how much. The idea is to give the output tank enough kick to get it to swing.

So you amplify the carrier with class C and modulate the plate. I've seen projects which do this with bipolars. One that comes to mind is an old Radio Electronics article for a uWave ATV commo system using gunplexers, but that can't be right since gunnplexers are modulated at the gunnplexer. I think it was another ATV project. If I ever find that old article I'll letcha know.

In a tube setup the RF amplifier should be operating in class C and the power audio amplifier should provide nice linear modulation to the RF amp's plate supply. In fact* one needs to provide sufficient excitation to the RF final, too, lest the thing go into a current limited mode on the modulation peaks.

Presumably you could make a REALLY EFFICIENT setup with transistors by operating the RF final in class E, but you get that pesky capacitance problem back...

* So I understand, I'm just a tube wannabe.

You are only scratching the surface. Check out the Harris DX series of high power AM transmitters. It will blow your mind away. Basically, the instantanous RF output power is synthesized by turning on 0 to 64 fairly low power (~KW) modules. I don't know what the sampling frequency is, but probably >20 KHz.. All modules are driven by a square wave signal at the carrier frequency. There is no modulator.

An ordinary masonry drill is perfect.It goes through it like cheese. The material is basically quite soft and can be easily shaped with an angle grinder and a cheap diamond cutting disc (those for cutting bricks, flags etc) . For final levelling use various grades of car 'wet-n-dry' (Silicon Carbide paper) and finish using Silicon Carbide (or even diamond!) 'lapping paste' slurries.
(nb. for rust stains soak in oxalic acid)

OK - I'll try that out on some off-cuts, assuming that such
things are available.

Otherwise - I'm collecting various bits of metal to make up a
bug key but am distracted by vertical antenna and its ATU.

I am trying to conceive of a minimal switching scheme to accommodate
the 10 ATU configurations discovered so far....
Straight through
Series C
Series L
Series C-L
"L" network with C on TX side
"L" network with C on ant side
"PI" network
"T" network
Parallel tank, series fed
Parallel tank, parallel fed

No, that's plate modulation. Class C is when the active element
conducts for less than 180 degrees of the cycle. A lot of times
when they plate modulate, they'll also apply the modulation to the
screen grid or even the control grid or previous stage. :-)

Cheers!
Rich

As you presumably know, that's just 100% AM.

It depends on how you define "linear" basically. But the term is a
total misnomer in RF amp terminology and very misleading. I can't
understand how it got there. :-/

Don't forget that you cannot really modulate a 'linear' amplifier by
varying the supply rail (which is what 'plate & screen' mod does). The
modulated stage has to be non-linear (eg Class C) where the power output
varies as the square of the supply volts. If the PA was biassed in Class
A, there wouldn't be any modulation.
Ian.

Can't blame 'em! Given that the audio power level needs to be
commensurate with the transmitter's RF power output level, using final
plate modulation with a 500KW TX might be a more than a little
inefficient. :-)

Certainly there would be no *amplitude* modulation, but that doesn't
preclude FM and various other schemes.

Many draw it out first by hand on paper, instead of using SW as it is
easier.
You have to enter in all the nodes and connections anyway.
Make all corrections on paper first, then put in the final. several programs
out there.

I get my used marble from our town's recycling center. You'd be
surprised how many "trophies" are thrown out. I find the side I want and
disassemble it. I even use them for heat blocks when I am doing some
heavy duty soldering. If they crack, I toss them. And...the price is
right!

>understand how it got there. :-/

Let's say that you have an audio amp with an input resistance of 1000
ohms and that, with a 1V input, it puts 10 volts across an 8 ohm load.

That's a voltage gain of

Vout 10V
Av = 20 log ------ dB = 20log ---- dB = 20dB
V in 1V

and a power gain of

Pout 12.5W
Aw = 10 log ------- dB = 10log -------- dB ~ 41dB
Pin 0.001W

Now let's say that you up the input voltage to 2V and that the output
voltage goes to 20V. That's still a voltage gain of 20dB and a power
gain 41dB.

Finally, let's say that no matter what voltage you apply to the
input,(up to some reasonable limit) the output voltage is always 10
times higher. That's a linear amplifier.

It's no different with RF.

Let's say, for example, that we have an RF amp with a 50 ohm input and
output impedance and that with a 1 watt input it puts out 10 watts
That is, it has 10 dB of power gain. If it's a linear amplifier and
we exercise its input according to the following table, the
relationships given in the table will be true. If it isn't, they
won't be.

```
Pin Pout Aw Ein Eout Av
W->50R W->50R dB V->50R V->50R dB
----------------------------------------
1 10 10 7.07 22.4 10
2 20 10 10.0 31.6 10
3 30 10 12.3 31.6 10
4 40 10 14.1 44.7 10
5 50 10 15.8 50.0 10
6 60 10 17.3 54.8 10
7 70 10 18.7 59.2 10
8 80 10 20.0 63.2 10
9 90 10 21.2 67.1 10
10 100 10 22.4 70.7 10
```

So, that should take the mystery out of why it's called a "linear amplifier" :-)

OK, some more stupid tricks.
In Jr. High school science fair some kid
brought in a one tube radio, powered by
a 1.5v A battery and a 90 volt B battery.
Radio wasn't working so some brainiac
said 'test the batteries'. How do you test
them? Kid said he tested transistor radio
batteries by touching them to his tounge,
to taste the sour a good battery caused!!!

Well he tried that with the B battery!

PS...It was VERY GOOD!!!!!

(just how far did he threw that battery
across the room, I forgot!)

Actually I've built *several* class C RF amps, John. However, I
wouldn't call any of them linear. You will be aware than linearity
starts to go out of the window when Class A slides into Class AB and
beyond. Let's not have an argument over definitions. It's an open
invitation to John Woodgate. ;-)

Nonlinear? Yes. Class "C"? No.

From http://sound.westhost.com/class-a.htm :

"
Class-A Output device(s) conduct through 360 degrees of input cycle
(never switch off) - A single output device is possible. The device
conducts for the entire waveform in Figure 1

Class-B Output devices conduct for 180 degrees (1/2 of input cycle) -
for audio, two output devices in "push-pull" must be used (see
Class-AB)

Class-AB Halfway (or partway) between the above two examples (181 to
200 degrees typical) - also requires push-pull operation for audio.
The conduction for each output device is shown in Figure 1.

Class-C Output device(s) conduct for less than 180 degrees (100 to 150
degrees typical) - Radio Frequencies only - cannot be used for audio!
** This is the sound heard when one of the output devices goes open
circuit in an audio amp! See Figure 1, showing the time the output
device conducts (single-ended operation is assumed, and yes this does
work for RF)

Class-D Quasi-digital amplification. Uses pulse-width-modulation of a
high frequency (square wave) carrier to reproduce the audio signal -
because of frequency limitations (and the fact that they nearly all
seem to sound disgusting), many are only suitable for industrial
control of motors and loud but crappy sub-woofers (this may change if
transistors with an infinite bandwidth become available soon - yeah,
right!) All Class-D amps have a major limitation in the output filter,
whose response is highly dependent on the load impedance.
"

>If the PA was biassed in Class A, there wouldn't be any modulation.

There could be; all that would be required would be for the gain of
the stage to vary with the modulating input. I don't believe there's
a constraint on class A biasing which inherently precludes a class A
stage from being modulated.

==========
Yes that will do . I drilled a slate base (similar to marble) for a pump
key .
It might be helpful to drill with the marble immersed in water.
This method also enables drilling in glass , for example to fit a
feed-through for an antenna (single glazing of course)

Really? I'd _love_ to hear your explanation for why that "happens".

I've heard a lot of amps that sounded pretty good at both low and high
volumes, and in between, and they've almost all had class AB outputs.

>Let's not have an argument over definitions. It's an open

> Bob in phx

Two programs come to mind for drawing schematics. One is
TinyCad...don't let the name fool you, this is one powerful, yet easy
to use piece of software that will draw just about any type of
schmatic, and it's freeware. You can find it at:
http://tinycad.sourceforge.net/

Another is my personal favorite is EAGLE. This will not only draw
schematics, but will convert the schematic to a PCB, and it even has
an autorouter. It is a commecial program with features up the kazoo,
but also comes in a limited freeware version that can do most of the
work that any amateur or hobbyist needs. You can find it at:
http://www.cadsoft.de/

You can be drawing schematics with TinyCad after carefully reading the
help files for 20 minutes.

Eagle is a different story. This is an amazingly powerful piece of
softwre with a longer learning curve. It's my opinion that you'll find
it useless if you don't plan on spending 2 or 3 hours with it going
over the tutorial and practicing a bit. If you do put in the time,
Eagle will knock your socks off.

These programs and many more are available. A simple search on Google
for "schematic drawing software" came up with 366,00 hits. Now, many
of these hits were "about" software, but there were certainly many
that went to software sites.

Hope this helps you.

I'll make up some switches out of brass rod - what I
have in mind is something like a large banana plug & socket
combination activated by nylon or PTFE rods. (I don't envisage
one FG rotary switch - I'll do it with separate switches,
possibly with some interlocking along the lines of
old railway signal box practice - I've enough books here
on that subject!

Primary doodles indicate that the antenna could be left
permanently connected to the inductor and one of the C's,
except in the case of a "T" network when it needs to be
connected to the other end of the said C.

There won't be any relays. The vertical antenna to the base
of which the ATU will be directly coupled is about 10 ft from
the shack and what I have in mind to use is a series of
activating rods - cunningly hidden/faced by a small picket fence.

The only area of development I haven't yet sussed out is how
to pass the operating rods into and out of a sealed (to keep
out the rain) chamber. Perhaps something like the stern
gland of a ship's propeller shaft might come into play here.

PS. Don't expect any reports of rapid progress - mechanical
contrivances seem to take me an age, and I'm also undertaking
my own "vibroplex" bug key at the same time (Hence this
thread about marble slabs) . Mechanics is frustratingly slow.....

1. In software, you get an idea, and a couple of hours later, your
prototype is working well and exciting you as to the possibilities
of the next version.

2. In hardware, you get an idea, and a couple of days later, your
prototype breadboard is singing along.

3. In mechanics, you get an idea which requires 10 components,
and one week later you're lucky if you've managed to make the jig
for machining the first of those components!

>It's an open invitation to John
>Woodgate. ;-)

Oh, thank you, Paul. Remind me to invite you to explain something one
day.

People are using 'linear' in two different senses. For audio, in fact
for any amplifying stage with an **untuned load**, linearity requires
linearity of output current with respect to input voltage, (Class A
single ended or push-pull, Class B push-pull).

But with a **tuned load**, 'linearity' can be achieved even with Class C
biasing. This is why linearity in this case is defined as output power
being proportional to input power.

With a **tuned load**, the output power also depends more or less
linearly on the supply voltage, so amplitude modulation can be achieved
by varying the supply voltage.

Feed the 5 MHz to both inputs of a high level DBM. The output will be sum
and difference, kill the DC component with a 0.1 uF coupling cap and you
probably can use the 10 MHz result. If not, a little low pass filter to get
rid of the higher frequency responses will make it useable.

I recently used DraftChoice for Windows (a downloadable shareware program) to reconstruct the schematic of an HP lab supply.

I created symbols for all the part types and then put them down on the screen (on grid) roughly where the parts were on the board. Then I connected them together with three colors of lines (one for each side of the board and one for flying leads). Then using the alter/rubber tool, I stretched the lines to put the parts in some obvious order that made sense to me. The rubber function stretches lines without distorting symbols. When the parts were all where I wanted them, I replaced the original colored lines with black ones. The result was a very fine schematic.

The big weakness of this program is its limited export capability. But it is very easy to work with and saves me a lot of time. If you get a copy and want a symbol file of my electronic symbols, email me and I will send it. I have a blank drawing file with the text set to .1 inch high, .1 inch grid and this symbol file included, to start any schematic. Then I save-as a new named file.

>

Joe -

The 91-MC4M connector was originally made by Amphenol.
In the 1980s, Wire Pro (WPI)acquired several of the commercial product
lines from Amphenol.
http://www.wpi-interconnect.com/salem.htm

The 78 and 86 Series of Commercial Plugs and Accessories as well as the 80
and 91 Series Microphone Connectors were two of these product lines acquired
at that time.

WirePro has the normal distributors: Allied, Newark, Arrow and ECCO
(Chicago)
http://www.eccochicago.com/ecco/index.asp

This surplus company says they have 580 in stock and the price is less than
$ 10) !
http://www.electronicsurplus.com/commerce/catalog/product.jsp?product_id=68641

Newark On-Line (just down the road from me) says they have it: Newark Part
number 39F016 -- and over 500 in stock at $ 10.58
http://www.newark.com/NewarkWebCommerce/newark/en_US/support/search/searchResults.jsp?QTex
t=39F016

This price is definitely from the audio (gold plated) audience = $ 26.00 !
http://www.oaktreeent.com/Vintage_Style_Microphone_Cables.htm

Ken's Electronics wants $ 16.00 for his connector (no wonder early CB died)
http://www.kenselectronics.com/lists/micplug.htm

I am not. For a normal ham amp to be linear it can not be biased class C. Class C will not reproduce a SSB or AM signal. It only works with constant signal levesl such as FM or CW. The tunes circuit "rings" and reproduces the missing portion of the sine wave of a single frequency. It can not do this for signasl where the amplitude is constantly changing such as SSB or AM.
As a circuit is baised from A to B to C portions of the waveform is clipped out. Class B can be used for audio or rf if it is in a push pull circuit so that as one device (tube or transistor) is cut off the other is conducting on the other portion of the cycle.

The term linear is now being used incorrectly for almost any RF amp even if the amp is biased class C. While it is not linear many use the term linear when the word amplifier or class B or C ampifier should be used.

Any class (A, B , C) of amp can be plate modulated for AM. It is then not really an amplifier.

There is also a fractional stage - a 64 stage AM modulation would sound
quite nasty, so an analogue signal is added to make up.

There is also a 'spare stage' dthat can be switched in if one of the
stages fails.

Nice stuff, but the only really interesting thing IMO is the output
combiner. The rest is just 'how do we make this digital'.

We weren't talking about components with perfectly linear transfer functions, _you_ were alluding to deterioration of input-to-output linearity in systems using different driver biasing schemes. Or so I thought, when you said:

"You will be aware than linearity starts to go out of the window when Class A slides into Class AB and beyond."

And I'll repeat:

"I'd _love_ to hear your explanation for why that "happens".".

But never mind, now that Woodgate's cleared it up there's no need for you to embarrass yourself further.

Just an obsevation... when you enclose a word or words in double
asterisks, my reader no longer renders them in bold, thus removing
the intended emphasis. IIRC it's the double underscore enclosure
that causes my reader to underline the text.

We now return you to our regularly scheduled terminology debate.

Small quibble:

you need to add "for a large enough drive" to the above. For small drive
levels the drive and the device gm control the output power.

Yes. They work very well (even more so the diamond tipped fitments) but
take a god awful amount of time to process any useful areas.

The 'select 1 of 10' ATU would seem a grade 1 mechanical-electrical
juggernaut of switches, relays?, screening cans, adjustable inductors
(roller coasters?), variables caps, connectors and knobs. I wish you a
interesting journey :-).
During a radio phase I think I also tried 'em all. Concluded they're all
much-of-a-muchness and finally settled on a 2 component "L". (The human
ear's 'Db' response seems to make a bit of a mockery of equipment technical
spec's :-).

I think this is right:

If this isn't the slow modulation case, for a single device RF output stage to work as a linear you need to bias it to about the point where gm is 1/2 the "mid current" gm. This makes the stage class AB.

If you want to go towards class B or C there are things you can do in the slow modulation case. Basically as the RF input increases, you move into class C and as it decreases you move back towards AB. Moving to class C lowers the output power for large signals a bit so the AB class's standing current can be reduced by some amount.

I disagree with this. If the stage puts out more RF than it takes in, it
is an amplifier even if the purpose of the stage is to be a modulator.

> understand how it got there. :-/

From basic systems theory:

A system S is linear if and only if for any two input signals x1 and x2 that generate the output signals y1 = S(x1) and y2 = S(x2), and for any two real constants A1 and A2, the output signal y = S(A1*x1 + A2*x2) is equal to A1*y1 + A2*y2.

This condition is approached with a properly adjusted RF linear amplifier, even one operated class AB or B. It is _not_ approached with a class C amplifier.

So if you define "linear" the way electronics engineering professionals define "linear" a class A, AB or B amplifier can be made to act linearly, more or less, and a class C amplifier cannot. So the term isn't a misnomer, and its use is obvious.

Yeah, exactly what I was wondering about, how do they combine the outputs?
They imply that they are combining power, but I suspect they are adding
voltages. BTW, the modules are not all the same. As I recall fom the WLW web
site, 60 are 1-2 KW, 1 is 500W, 2 are 200W, and 1 is 100W. They claim
something like 90% efficiency from 3 phase 60~ in to RF out. Also, there
must be some huge bandpass filter on the output to suppress the sampling
frequency.

I'd always understood that it refered to an operating frequency range
with a wide bandwidth, therefore suited to FM or frequency hopping.

The point that the discussion has reached is that the term 'linear' IS
used in a different sense that includes Class C, whether we like it or
not.
>
>So if you define "linear" the way electronics engineering professionals
>define "linear" a class A, AB or B amplifier can be made to act

Like several other posters, I'd be very surprised to see a counter that required
50:50 M/S ratio. Jitter in that would be extremely critical. All counters I've
seen use edge-triggering off the same edge for all timing/gating.

>A few turns on a teeny ferrite ring 1:2 transformer, centre-tapped
>secondary, and a couple of diodes will double the frequency without any
>power loss.
>
>
>
What Reg is describing here is undoubtedly the BEST and EASIEST and MOST PREDICTABLE way to double the frequency of a signal. You can also use it to obtain x2 and x6 etc, but with reducing efficiency. I have frequently used it to get signals up to about 1000MHz.

It s exactly the came circuit as for a bi-phase rectifier on a mains power supply, ie transformer with centre-tapped secondary and two diodes.
The shape of the output waveform is the same as what you get from the rectifier circuit, ie a series of half sinewaves (all +ve or -ve, depending on which way you connect the diodes). This contains an infinite series of even harmonics and no odds (including the fundamental).

For the mathematical, the theoretical level of each harmonic can be predicted from a knowledge of what Mr Fourier says about this shape of waveform (from the coefficients associated with each frequency). See below for several examples (just click on the examples at the bottom of the page).
http://www.efunda.com/math/fourier_series/fourier_series.cfm

In theory, there are no losses. But you are splitting a single signal into a load of even harmonics, so the level of each must be less than the original signal.

In practice, there ARE losses (in the diodes and the ferrite). From memory, the x2 is about 8dB down, x4 is about 16dB down, x6 is about 24dB on the original signal. These ratios are essentially independent of drive level, provided you have sufficient to overcome the knee of the diodes. If you are after the x4 and x6, you can actually do things which reduce the loss somewhat, and make the multiplication more efficient. But I digress...

Finally, a big advantage of this circuit is that the odd harmonics are well suppressed. They are not zero, but are typically 30 - 40dB less than the adjacent evens (depending on the balance of the circuit). This makes any filtering (if the application requires it) SO much easier.

Cheers,
Ian.

Absolutely true!.
About 30 years ago I picked up a rake of bits and pieces from an amateur who operated in the 30's. Drawers full of brass stud terminals, connectors, wire crimp ends, knob pointers etc. nickel plated screw-downs etc. They're much too nice to use for normal construction and I've been waiting for a project to turn up where it's worth spending the time to make use of them. (maybe have to invent some kind of art-deco project) The Vibroplex idea is just this kind of much-sweat-n-toil, 'object of beauty', that's actually worth passing down from generation to generation. All the electronics and programming I've ever done, is so GD transient that I'm lucky to remember any of it after even a couple of years.

AM shortwave broadcast stations are spaced at 5kHz intervals so the receiver was probably designed with that in mind. For simplicity's sake, they will have used a single loop design in the synthesiser with the aforementioned 5kHz as the PLL reference frequency. Had the receiver been meant for sideband/CW operation, it would then have had the ability tune in smaller increments.

Generally you get what you pay for :-(

Cheers - Joe

Curious. I have a book (by an author whose name I can't recall off
hand) called "High-Linearity RF Amplifier Design" in which said author
claims that a linear RF amplifier is one in which the transmitted
signal, regardless of however non-linear it may be, is passed through
sufficient filtering to clean it up! Work that one out if you can!

I bought my son one of these and he is very happy with it.

Hank-
Alas, Houston has become a wasteland for electronics scrounging from what I've been able to tell.
The EPO outlets used to have a reasonable amount of miltary and commercial surplus, but they've become commercialized towards computers, and the other garden variety electronics stores only carry the traditional stuff. Fry's is pretty cool, but obviously no surplus. Madison Electronics used to be the cats meow, but that was many years ago.

I assume you've heard of dallas' 1st Saturday sale, which occurs this coming weekend.
http://www.firstsaturday.com/ it's become computer-centric, but most of the electronics stuff (i.e. ham) start setting up around 7:00AM in the back area.

Also Ft Worth has Nortex
http://www.montagar.com/~patj/nortex.htm
Which is waay cool to browse, but don't expect to find any incredible finds or deals.

Too bad Houston isn't more like Dallas wrt surplus goodies.

regards
-dave

If you are putting RF in and getting RF out at the same frequency, in any reasonable case the circuit is acting as an amplifier. The circuit may well oscillate when no input is applied. This sort of amplifier was very common in the past and still is somewhat common.

A super-regen receiver is the most obvious example. Many tube based FM receiver designs had a FM detector that would oscillate with no input signal. The "burst lock oscillator" in a TV is in fact a very narrow pass filter and amplifier when there is a burst to lock to. With no burst it oscillates.

If the conduction angle is less than 180 degrees it is class C. Note that
I said "you move into class C" this means the amplifier isn't always
running as class C. It only runs in class C with large signals. Since
the large signal case is were the losses really matter, this sort of
design will work quite a bit better than a simple class AB circuit.

Tube class-C amps often self-bias (via grid rectification) when
operating normally. Without drive, they often have high, sometimes
dangerous, idle currents.

But some of these sets did have a 'claifier' or 'fine tune' knob that
pulled the reference rock a little to allow for off frequency stations
and SSB. For ssb you could also just move the BFO a bit too.
The RS rx in question probably doesn't have either of these controls.

Toobz? I was talking of transistors. Many tranny designs for Class C
RF utilize self-bias, too, but there is still no quiescent current!

What makes an amp Class C is a low conduction angle while operating.
When it's not operating, is has no class at all.

Bob -

You need to use a temperature controlled soldering station (period)

The Haako 936 has already been mentioned -- I actually do not own one.

I use the Weller TCP series which has been around for 50 years -- and is
very easy to repair.
Many list members use it from surface mount (1/32" conical tip) to
boatanchor repair (1/8" screwdriver tip)
Collins used them when Weller first marketed them on the assembly lines for
the Collins "S" line as well as
rework stations.
http://www.cooperhandtools.com/brands/electronic_applications/index.htm

Weller / Cooper Tools introduced "their answer" to the Haako 936 18 months
ago, which is the Weller WES51.
This station is readily available for same price as Haako. Both of these
stations are available at Fry's Electronics here in Chicago.
Almost all of the Weller stations are also available at TriState Electronics
in Mt. Prospect, IL

Weller also has just started in annual "Fall Promotion" (September 1 -
December 31, 2004)
http://www.cooperhandtools.com/fallpromo/index.html

If you would like to talk to a dealer for various alternatives ->
Consolidated Electronics in Dayton, OH is a good dealer for you.
Ask for Steve Coy (who is a ham and on the Dayton Hamvention committee).

Warranty repair for Weller is available in Apex, NC

If you desire one of the Weller stations I have restored or found a broken
WTCP unit you need repaired, contact me directly.

Greg

Bob,

One more point, IF you do order via the Internet --
order your selection of tips at the same time as the station (especially
with Haako from TE Equipment)

Many have a minimum order of $ 25 to $ 40 -- depending upon firm.

If you want suggestions on tips, let us know what you are soldering -- I
have a recommended list of abut 4 tips varieties.

Well its that time of year again, and school has started.

Middle schools, high schools and youth organizations (e.g., 4-H, Boy Scouts,
Girl Scouts) often look to their communities for assistance in developing
"experiential"
learning programs and knowledgeable volunteers.

Electronics and computers are often at the top of the lists for external
assistance by these educational organizations.

If your assistance is asked for, one of the biggest stumbling blocks that
you may face is gathering the proper educational materials
or developing actual projects for these organizations or groups.

One web site that I would highly recommend is the Electronics Club web page.
This web page was designed by Mr. J. Hewes for the students (pupils) at the
Kelsey Park School (UK).

Electronics Club - Kelsey Park School
http://www.kpsec.freeuk.com/index.htm

The AmQRP / NorCal Keyer Kit is also a possible kit for educational usage
http://www.amqrp.org/kits/NCKeyer/index.html

I already received my request from a new middle school teacher 2 weeks ago !

Perhaps a tad OT but an enjoyable read. The Electronics Club material may
be useful in our Boy Scout/Cub Scout troop.
Thanks,
Paul

Hey Henry:

I was told last week that in Missouri City is Charlie's Airwaves. He sells renovated antique radios and he supposedly has some interesting surplus. If I recall correctly Missouri City is South of Houston on I59, about 15-20 minutes. If I can find a map I will try to find out if this is correct and post it.

His card I have here says C.B.s, Antennas, Stereos, Microwaves, TVs, Satellites, RV parts, Accessories.

2547 Cartwright Rd.
Missouri City, Texas
281-499-5214

There is also O&E Electronics on Shephard about 3 blocks south of the North Loop 610.

713-880-3055

This place is a major mess, but he does have a lot of odds and ends. He has a large rack of used test gear. Also has a lot of NOS tubes, but a bit pricey. He has tons of Sam's for sale. They mostly have parts for repairing old TVs and VCRs, etc. Lots of weird ICs.

Vintage Sounds sells antique radios and phonographs. They are the HVRA crowd. Lots of interesting pieces, all restored. Also have lots of tubes, some books, records, very few parts except parts for acoustic phonographs. They have horns, reproducers, knobs, etc. 713-468-4911. In the Hart Antique Center on Fondren about 1/4 mile south of Westheimer. On the right when heading south. Open till 6, 7 days.

The other EPO is right down the road from Vintage Sounds, on Fondren. Just keep heading south past the elementary school, it is on the left about another mile. Go through the light at Richmond when heading further south on Fondren.

The Houston traffic is much easier before 2pm. Happy Hunting, Mark

I watched a 16 year-old nearly fix a tough mechanical problem with a
Rowe/AMI stereo jukebox and he was halfway there towards fixing my IF coils.
Bite your tongue.

HK: To get to Missouri City go south on 59 and
exit Texas Hwy 6 (a few miles outside city limit). Turn left on 6 and go a
few miles. This map shows that Cartwright intersects Texas 6 as Road 3345.
Turn left on 3345. If you get to Road 1092 you've gone too far so do a 180
and go back to 3345. You may already know where it is. Good Luck MH

2124. NBFM from DDS chip

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-08-30 05:50:10 UTC
From: MikeN <mnewman@clear.net.nz>
Message-ID: <1jf5j0dqvqu83v0ebcs4lu07citgrb1v78@4ax.com>

Hi

Has anyone given thought to producing NBFM using the AD 9854 or
similar DDS chips, for multiplying or heterodyning up to 2m or 70cm.

This could be an interesting project. I see Analog Devices has an
application note AN-543 which describes a stereo WBFM generator with
output on 90.3 MHz.

A fatal attitude to progressing with useful projects in
the mean time!

I had this approach to a number of things until someone
pointed out to me that the most expensive and luxurious
item that is already in your junk box is much, much
cheaper than the shoddiest thing you can buy!

Now, if it's to hand, and will do the job, I use
it and move on.

For example, I had a 28MHz 2-ele beam that was in
its original packing for many years - then the aluminiium
tube got used to make the legs of a clock-testing horse
last year.

At the Wimborne FRS rally, there were two identical models on adjacent stands in the flea market. One was priced at £15 and the other at £50 or £60 (I did comment on the price contemporaneously, but now I've forgotten it because it wasn't the one that I went for)

I suspect that with the CBisation of Ham Radio, especially here in Britland with the M3/CB Fools' Licence, that more and more of these will come on to the second hand market when increasing numbers of CBers-Masquerading-As-Radio-Hams have no idea what to do with them, what with their buy-in-a-box complete stations with auto antennae tuners enclosed.

This will become an increasing problem in Yerp when the
WEE Waste directive takes hold - no company will be able to
dispose of old electronic eqpt other than through a licensed
waste operator, who must in his turn be able to show that he
has passed it on to similarly licensed people.

Scrap electronics will become a thing of the past for the enthusiast.

Don't buy Draper tools!

I recently purchased a 100W soldering iron from them.....
1. The bit fell out and burnt the carpet after some 10 minutes use.
2. After being left on for an hour or two (cumulative annoyances in
trying to solder a PL259 onto the coax braid), the tip has a large hole
in the end.

Not having learnt my lesson, two days ago I purchased a pair of rotary
pliers for punching holes in leather - after punching 3 holes, 4 of the
punches fell out of the rotary selector, where they were supposedly
a force fit.

(Buying Chinese-manufactured goods can spoil your love
affair for engineering - you get a "Chink" in the amour!)

I forgot the SPC, but that appears to need a differential
capacitor that I haven't yet obtained (or made).

Also, ISTR reading somewhere (that I cannot find) that
the SPC arrangement is very lossy, and can result in
3/4 of the power being lost in the ATU itself)

For the other configurations below, I've worked out that I
need only 8 simple on-off switches to effect all the configurations
below, including the safety issue of isolating the antenna from the
TX and earthing it.

Computers (or more likely computer games) might be at the top of the
list, but kids nowadays don't seem to give a f**k about electronics in
general. Hardly surprising, given the superficial garbage we force
feed them via TV, film and "newspapers."

I've been considering it for years; it should work OK as long as your sample rates are high enough. In fact there are nice, small DSP chips now that should implement a good FM receiver to go along with it for a complete transceiver.

It's never been a paying project for me, and it's never made it to the top of the "home brew" pile, so it stays in "would be cool" land.

I wouldn't be surprised if this wasn't the algorithm used in DSP generation
of FM.

It was used to generate four part music, in software, back in the early 80's
with a 0.9 MHz 6809 CPU.

>I forgot the SPC, but that appears to need a differential
>capacitor that I haven't yet obtained (or made).

The SPC circuits I've seen (including the classic design in the late '90s ARRL Handbook) does not use a differential capacitor. Its output capacitor is a dual-section non-differential type - the two sections track in parallel.

I have seen some T-type tuners which use a differential capacitor, with one section being the input cap and the other being the output cap. MFJ sells one of these. These are advertised as being more convenient, since establishing a match requires tuning only two controls rather than three. However, I doubt that this arrangement results in the most efficient match.

>Also, ISTR reading somewhere (that I cannot find) that
>the SPC arrangement is very lossy, and can result in
>3/4 of the power being lost in the ATU itself)

I don't think that's a specific characteristic of the SPC - it seems to be true of T tuners in general. The T configuration does provide a wide matching range, but in the case of very low-impedance or highly reactive loads the "match" may result in extremely high circulating currents through the coil, with the resulting high losses. A "T" tuner with sufficient reactance in the components may let you establish a "match" for a short-circuited load... but you'll end up dissipating almost 100% of your power in the coil. The SPC probably shares the same characteristic.

>similar DDS chips, for multiplying or heterodyning up to 2m or 70cm.

Doesn't the smaller DDS chips have serial loading of the phase
accumulator addend ?

To get communication quality audio, at least 8 kHz sampling rate is
required. If the phase accumulator addend is 32 bits, the serial clock
would have to be more than 2 MHz.

On 9854, the 14 bit phase offset word could also be used, thus
reducing the serial data clock to 1 MHz, well below the maximum 10 MHz
data clock frequency.

Maybe the FSK ramp rate could be used to reduce the clock rate needed.

>This could be an interesting project. I see Analog Devices has an
>application note AN-543 which describes a stereo WBFM generator with
>output on 90.3 MHz.

A stereo WBFM generator would require at least 120 kHz sampling rate,
which would be quite trivial with parallel tuning words, but would be
quite demanding if 32 or 48 bit tuning words needs to be loaded each
audio sample time.

Recently obtained a VHF Portable Radio that has NO information as to
Manufacturer or Model of Unit.
From info already in the unit, I know it is:
VHF Wide Spaced / 1W & 5W / 15 Channels / CSQ / Has a battery marked as
B-706 / Has a sticker on side marked KH142UH / PC Boards inside are marked
KOMBIX PC-181 & PC-177.
I have listed a link to a picture of this unit below.

Any assistance with this unit's Identification, Manuals etc... would be
appreciated...then I have to find a Programmer ! !

This comment reminded me of a High Current Horror Story related to me by an older friend. In his youth he repaired radios, hi-fi systems, and the like. One well-heeled customer had large, expensive speakers at the room corners, with the hi-fi in the middle. He'd put the speaker wiring in the walls. For connectors, he'd used ordinary mains AC power receptacles, with matching cord and plug on each speaker.

When the repair was finished, my friend plugged the speaker back into the outlet. He knew exactly what had happened the moment he plugged it in when he heard a monstrous, deafening hum -- but even then it was too late, the speaker was cooked. Let's see, 120^2 / 8(*) = . . . now, that's LOUD!

Roy Lewallen, W7EL

(*) and I suspect that the speaker impedance was somewhat lower yet at 60 Hz.

And you reminded me of something too. Not really a problem, but could
have been.

When I was working on mainframe computers in the 70's we installed a new
machine in Europe. The power for the computer was supplied by a big
motor generator with an output of 3-phase 208 V 400 Hz (or was it CPS
back then?) power to the computer. I learned from the customer that they
discovered that a wiring error had routed the motor generator power to
the wall sockets in the computer room.

I told the customer that it was very good they had found this problem
before people used the sockets. If the cleaning lady had come in and
plugged a vacuum cleaner into the 400 Hz power, it would have probably
sucked all the air out of the room. :-)

This from a summary of the WEE:

"The Waste Electrical and Electronic Equipment Directive (WEEE) aims to minimise the impacts of electrical and electronic equipment on the environment during their life times and when they become waste. It applies to a huge spectrum of products. It encourages and sets criteria for the collection, treatment, recycling and recovery of waste electrical and electronic equipment. It makes producers responsible for financing most of these activities (producer responsibility). Private householders are to be able to return WEEE without charge."

Sounds like they are concerned with the same mess we have here with computers and cells phones ending up in the dump.

Other WEEE info indicated that they are mainly concerned with dangerous chemicles in batteries, etc. It does sound like the inspection process would drive up the price of everything.

If they are trying to minimize the buildup of electronic waste as disposal sites they would probably encourge surplus dealers to take what they could sell. There is a limit to how much the dealers could pay for it. MH

Although I tend to agree with you about the interests of the younger generations, I also have to remember that my parents were probably worried that all their kids wanted to do was mess with them radio gadgets, and who would the world depend on to machine ball bearings? Somehow life stumbles on, and who really needs precision ball bearings anymore? We can use adaptive software to fix the vibrations!

Jim
thanks for a great tip! Downloaded the 2MBsetup-file. Runs great on my
XP machine and I am confident it will be very handy! Never heard of
this one before! Thumbs up!

Charlie's Airwaves is over pirced on almost every thing. Nice place to go and look & repair prices are not that bad. I remeber when the EPO Houston use to sell alot more surplus stuff that was like 3 years ago. Now the only surpul stuff they have is some computer stuff batteries power supplys and generators. I like the epo back in the day not it is just good to go & look you might find something you need. I am also looking for a good surplus electronic store within about 50 or so miles of Houston anybody know of any good ones.

On the SW bands, it tunes in 5kHz steps. On the MW band it tunes in 9 or 10 kHz steps, subject to your setup. Even though a station may transmit on a frequency between a step, the selectivity is wide enough that the nearest step will provide reception close to what it would be were it tuned right on.

If this would force the manufacturers, particularly Chinese ones, to
pay more up front to cover the environmental impact of their
products, then it is a good thing, even if it means consumers will pay
more as well.

For too long, importers of this cheap crap have been permitted to
operate with scant concern about where their products will ultimately
end up. They have been able to price their wares artificially low
because the true cost of manufacturing and ownership is not borne by
them. Why should they care? They don't have to pay the costs of
disposal!

About four to six times a year, I go to our local dump to deposit
refuse that is the result of seasonal cleaning. Every time I am there,
I see an enormous dumpster that is just FILLED FILLED FILLED to over
the top with late-model electronic junk of every description. It makes
me sick.......These items are totally useless albatrosses. No one can
repair them, cannabilization for useful parts is almost impossible,
and disposal in an environmentally acceptable manner is quite
expensive.

IMHO, These items should be put on a giant barge and sent back to the
country of origin with the caveat that a trade embargo will be imposed
against any country that refuses to take them back. Maybe when China,
Mexico, and other cheap-labor countries experience first hand what a
colossal pain it is to deal with the ass end of their product's
mercilessly short life cycles, maybe they won't dump quite so much of
this junk on our shores.

Hi Group,

I have a crystal marked 100MHz, it the smaller package found in the CBs.

What I want to do is connect this up to a ECL or Fast TTL and get a 0 to 5 Volt square wave output that can drive 50 ohms with 2.5 volts or more.

Anyone have a good circuit or suggestions?

Tnx de KJ4uo

It will oscillate at the fundamental, not the marked 100 MHz overtone
frequency. At 100 MHz, I'd guess that's a 7th or 5th overtone cut.
Most likely 7th, 20 MHz is about the limit for fundamental crystals.

I doubt that the Chinese are really worried about what we want. Communists
are not known for having much of a conscience.

I recall seeing a TV documentary months ago about the recycling of old computers. They bust them all up and sort the plastic, etc. Seems they were breaking even or even making a profit. The problem is getting them before people throw them in the dump. This was a huge operation with conveyors belts and big piles of dead or near dead computers. I think they had something like what the tree trimmers haul behind their trucks. Grinds them up into little recyclable chunks....sort of like spam. Grunt labor stands there all day by the conveyor belt with Tylenol and rubber gloves. At least they can claim they are in the computer industry. The last word in computer technology. <MH

Funny you should mention that, That's where a LOT of our surplus
(i.e. garbage) computers end up. They've got a growing problem in
China now about the recycling centers causing massive ecological
damage to the towns that they recycle in. From burning plastic
insulation off to salvage copper, and the chemical sludge from
stripping gold and silver plating.

One of the main reasons that we never seem to get sufficient control of our
pollution problem is the lack of pollution control in developing nations.
We must compete and pollution control is expensive.

Sacrificing human health for corporate profits is the global format. MH

That used to be the case, but 40 MHz fundamental crystals have been
available for some time. I've got some.

If you look at the WRTH _shortwave_ frequency list, much more than 95 % of the stations are spaced at 5 kHz multiples, as the ITU requires them to be.

Those that are not, seems to have problems with their frequency stability and may drift somewhere between. These are usually small private stations, in which the equipment has been hacked up by some local technician.

>
So how does one tell if the xtal is fundamental or overtone? Not for
xtals marked 100Mhz, obviously, but for much lower frequencies which
could be either..

I bet at least half of those is easily repairable ($5 in parts, an hour labour at most). Most people don't consider repairing because it is cheap to buy a new one. It's not the bad design per se. Just make the stuff more expensive (import taxes) and demand a 3 year warranty or so.

I can't say for sure whther this would work (items may just be dumped into the ocean), but it could be an idea.

I think lack of conscience is not a communist problem per se. This having been said, I know that at least some European communist countries, tried to make their design and manufacturing as solid as possible. Because in their philosophy there was no such thing as unemployment, and there often was a shortage of supplies, there was no reason not to put a good amount of engineering into their stuff. I can confirm 2 East-German black and white TV sets running since 1988 without needing repairs (and many more of those sets in continuous use in the Prague metro, if they were not drowned 2 years ago). Some radio collectors can confirm as well that East German and Czech radio's seem rather well built (alltough I have not seen too many of those, but what I have seen was nice).

I guess this is not for the garden variety crystals, but I've seen (can't
remember where) that IC etching technology has been applied to crystals
manufacturing which resulted in crystals of over 200MHz fundamental
frequency.

Easy. Look for resonances near 33.3MHz, 20MHz and 14.3MHz. Or...put
it in an oscillator circuit which favors fundamental mode and see
where it oscillates.

Cheers,
Tom

Suggestion: just get a 100MHz TTL oscillator. I believe Harold
offered you one last time you posted about 100MHz xtals a couple years
ago. ECL won't have 2.5V output, but I could supply you with a nice
little PECL 100MHz VCXO that you could easily trim to "exactly"
100MHz. It will deliver about 800mV p-p into 50 ohms.

Cheers,
Tom

I have used fundamental cut crystals on their overtones and overtone
crystals on their fundamental. NOTE, the frequencies will NOT be exact
harmonics/multiples. Somewhere I have information giving the typical
differences.

The crystal Colpitts is one sure bet. Stay away from circuits with
inductors and tuned circuits for a fundamental oscillator. Some IC
oscillators can give misleading results. They can pound the rock too hard.

here's some circuits thanks to GOOGLE:

This type is my favorite. Used in just about all Motorola channel elements
of Motrac through Micor and probably beyond.
http://homepage.tinet.ie/~ei9gq/tx_circ.html
Though seems to me, the lower cap should be 100 rather than 220pf, but they
are REALLY non critical. One page I found had them both at 1000pf.

Fig 7 looks the same:
http://www.northcountryradio.com/PDFs/column007.pdf

Discover Circuits also has a lot of circuits.
http://www.discovercircuits.com/O/o-crystal.htm

Very good memory! The crystals are called inverted mesa, and can go above 200MHz in fundamental mode. Most crystal manufacturers supply them. The prices were over $300 when I first started looking, but quickly dropped to the $30 - $40 range in 2001. I don't know the current prices, but expect they will be even lower.

Here are brief extracts describing the improved jitter performance, some performance degredation to look out for, and two typical ads.

Unfortunately, at roughly 40 MHz, conventional crystal oscillators hit a frequency ceiling.

A crystal's frequency limitation stems from the relationship between resonant frequency and crystal thickness. The ratio is approximately T = 60/F, where T is crystal thickness in thousandths of an inch and F is fundamental frequency in megahertz. The thickness of a crystal designed for 40 MHz is therefore 60/40 = 0.0015 in. = 1.5 mil. Crystals thinner than this 1.5-mil threshold are too fragile to withstand the mechanical stresses of oscillator production.

Several available techniques outflank the 40-MHz limit. Using these methods, commercial crystal oscillators can generate outputs of up to several hundred megahertz. Yet there's still a significant gap between the crystal-stabilized reference frequencies available and

the needs of today's Gigabit Ethernet, ATM, and SONET systems. In these applications, the datacom equipment builder must multiply, or upconvert, the crystal-oscillator reference frequencies to reach the gigahertz range.

Frequency multiplication tends to increase jitter as well as frequency, however. To minimize jitter at the gigahertz level, equipment builders have to start with super-low-jitter reference oscillators. But the higher the reference frequency climbs, the lower the final gigahertz signal's jitter. Naturally, crystal-oscillator manufacturers are developing generations of clock oscillators that raise frequency while simultaneously reducing jitter. Doing so requires advances in quartz-crystal technology, oscillator circuit design, packaging, and manufacturing (see "Oscillators Are More Analog Than Digital," p. 118).

Those manufacturers have long depended on two basic techniques, overtone and multiplier, to overcome an ordinary crystal's 40-MHz frequency ceiling. In the past year, a third and until now theoretical concept - inverted mesa - has proven eminently practical for achieving high oscillator frequencies (Fig. 1).

http://www.elecdesign.com/Files/29/1256/Figure_01.gif

http://www.elecdesign.com/Articles/ArticleID/1256/1256.html

The inverted-mesa crystal paves a route to high oscillator frequency, seemingly in defiance of a crystal's "thinness" limitation. Inverted-mesa oscillators can resonate a region of quartz only 0.00024-in. thick for 250-MHz fundamental operation. This value represents performance anticipated in the near future.

The crystal is created by etching a "well" in a quartz crystal blank (Fig. 1, again). The bottom of the well is the very thin area of quartz needed for high-frequency resonance. The thicker region surrounding it provides mechanical support and electrical connections. Both sides of the crystal are gold-plated to deliver excitation energy to the resonant region. That plating is continued to the crystal's outer edges for bonding to connecting wires.

Inverted-mesa oscillators operate the crystal at its fundamental, albeit high, frequency. Today's designs exhibit jitter below 5-ps rms. Because the technology is new, future improvements are promised in both jitter and frequency. The jitter performance of the overtone and inverted-mesa oscillators definitely stands out when compared with the multiplier type (Fig. 3).

http://www.elecdesign.com/Files/29/1256/Figure_03.jpg

http://www.elecdesign.com/Articles/Index.cfm?ArticleID=1256&pg=2

Inverted-mesa crystals

A new manufacturing technique uses chemical milling to etch the crystal thinner than can be done with conventional lapping machines. The devices produced in this process - inverted-mesa crystals - oscillate at higher frequencies than traditional quartz crystals, reducing the number of multiplications needed to achieve a given frequency. Fewer multiplications means reduced phase noise.

Inverted-mesa crystals can produce fundamental frequencies up to 200 MHz and higher. The two tradeoffs are a higher price and a faster aging rate compared to conventional AT-cut crystals. To make inverted-mesa crystals, the circumference of the crystal blank is masked off during etching, and the periphery is left thicker and stronger. The result looks like a snare drum. Typical diameters are 0.200 in. and thickness isless than 0.002 in.

The chemical milling process triples the price of inverted-mesa crystals. And because they're thinner, inverted-mesa crystals are more susceptible to packaged contaminants, which are always present to one degree or another. Inside the package, contaminants can deposit on this very thin crystal and affect its resonant frequency.

Because there is so little mass to the etched crystal, any contaminating particles are proportionately larger and have greater effect than they would on regular AT- or BT-cut units. This accelerates the crystal's aging characteristics. But in today's higher-bandwidth environment, these two tradeoffs are no impediment to achieving the higher performance now demanded of VCXO's.

http://www.raltron.com/corp/pdfspecs/news_inverted.pdf (42k pdf file)

200-MHz VCXO Employs Inverted Mesa Crystal

June 2001

By utilizing an inverted mesa quartz crystal, the VC-8000 VCXO combines higher frequency, lower noise, increased stability, wider pullability range, and faster on/off times than is possible with an ordinary quartz crystal. The device works as a signal-enhancing filter for asynchronous communication systems that embed their own content data, clock, and error-correction data. Acting like a high-Q filter, the unit re-generates the incoming signal from scratch and stops noise, jitter, or other perturbations from getting through, resulting in a re-generated signal that is noise free. A voltage controlled reference output frequency is up to 200 MHz, with less than 1 ps jitter, and an overall frequency stability of ï¿½30 ppm. Prices are from $39 to $49 each/10,000.

http://www.raltron.com/

High frequency fundamental-mode crystals are increasing in demand for applications such as precision high speed clocks, VCXOs and VCTCXOs. However, conventional crystal processing utilizing flat quartz blanks has limited the available frequency range to 55 MHz. Using higher quality, "swept" quartz, it has long been possible to produce fundamental-mode inverted mesa crystals with frequencies extending past 200 MHz. However, the higher cost of materials, coupled with slower production throughput have made these resonators undesirable for use in large volume applications. As telecommunication equipment designers continue to demand oscillators that operate at higher frequencies and still retain the smallest possible size and tightest stability, manufacturers have scrambled to fill this growing market. With the introduction of Champions CIM-32 Series, designers can accomplish these goals without breaking their budgets.

What next? Will we be pining away for East German and Soviet era
products like the Trabant, Lada, ZIL?

It's one thing to restore and operate an HT-32B/SX-115 but East
German consumer electronics?

The solution to the trash and recycling problem is a bit more
attention to repair and disposal on the design and manufacturing
side, and a recycling deposit.

If the stuff were easier to fix and upgrade, it wouldn't be pitched
out so quickly.

Can't do much about cell phones, portable CD players, and other
smallish items but the big stuff should be fixable or recycleable.

If new consumer electronics were tagged with a barcoded serial
number and a $1, $5, or $10 deposit levied on each item. The
recycling industry could pay people to bring the stuff back.

de ah6gi/4 - No chance of my 75S-1, SB-303, or SX-100 ever
going to the landfill.

I only had time to go to EPO on Fondren. Spent about 30 minutes and didn't find anything I couldn't live without. I was there a year ago and the main thing I noticed is that prices have gone up. If this is the case elsewhere, homebrewers are going to have to dig deep or look elsewhere.

No. Jitter is jitter is jitter, but is related to phase noise that is phase
noise that is phase noise.

Our newer systems back in 1985 used dual MG setup 400 Hz and 50-60 VAC

anyway, one of the tape drive units had failed, IBM arrived and was checking
power connections in the power supply (they call it a power tub).
Other IBM guy (new young pup) kept leaning on the control unit while
the old timer IBM guy was trying to probe the voltages at the breakers.
Almost gave him a large shock before we told him to get off our control unit.

Same young pup wants to get under the floor to unplug the large
power connector russelstoll 30 amp 3 phase, old timer grabs him by
his belt from behind, and saved his life !

IBM guy takes the rubber cord and then gently glances the RS
connector to the floor supports (all metal and gounnded with copper cables)
large sparks when he did this !

Young ibm pup almost pee in his pants.

Turns out somebody on work crew did not wire the ground cables properly
so the floor was HOT HOT HOT ! Good thing it was carpeted flooring in the
computer center.

Hi Paul,

Actually, I didn't write that. Those were excerpts from various
sites that discussed the pros and cons of inverted mesa crystals.

The main advantage of inverted mesa crystals is lower jitter (or
phase noise,) especially when you have to multiply to higher
frequencies such as the Ghz region. Inverted mesa crystals allow you
to start at a higher frequency, which reduces the multiplication
factor needed.

To answer your question, yes, phase noise and jitter are closely
related. Jitter is measured in the time domain and has units of
time, where phase noise is measured in the frequency domain and has
units of dBc. You can convert from phase noise to jitter by
integrating the phase noise curve.

There are many articles that discuss phase noise and jitter. Perhaps
the best are by Hajimiri and Lee:

Ali Hajimiri and Thomas H. Lee, "A General Theory of Phase Noise
in Electrical Oscillators", IEEE JOURNAL OF SOLID-STATE CIRCUITS,
VOL. 33, NO. 2, FEBRUARY 1998

www.chic.caltech.edu/Publications/general_full.PDF (441k pdf)

Thomas H. Lee, Ali Hajimiri, "Oscillator Phase Noise: A Tutorial",
IEEE JOURNAL OF SOLID-STATE CIRCUITS, VOL. 35, NO. 3, MARCH 2000,

http://www.chic.caltech.edu/Publications/phase_tutor.pdf (212k pdf)

Dean Banerjee also discusses this in his book "PLL Performance,
Simulation and Design"

https://www.national.com/appinfo/wireless/files/DeansBook_4_01.pdf

There is a worked example in "Measuring / Specifying Jitter in crystal oscillators":

http://tinyurl.com/4jzfc

Wenzel has an Excel spreadsheet to calculate Allan Variance from Phase Noise:

"This spreadsheet calculates the Allan Variance from supplied phase noise intercepts. Total RMS jitter over the specified bandwidth is also calculated."

http://www.wenzel.com/documents/spread.htm

Boris Drakhlis had two articles titled "Calculate Oscillator Jitter By Using Phase-Noise Analysis," Microwaves & RF, Jan. 2001 pp. 82-90 and p. 157, but they seem to have disappeared from the web. I could email them to you if you are interested, but they basically duplicate the above info.

Ken Kundert also has some info on noise and jitter on his home page:

http://home.pacbell.net/kundert/

Most exciting to me is Rohde has found a way to significantly reduce the phase noise in wideband vco's, which was previously dominated by varactor noise. I keep searching for more information, but there seems to be nothing in the USPTO or on the web. He sells modules but I don't have the url handy.

Maybe some info will appear as time goes on and more people use them.

Best Regards,

Mike

Generally speaking. it is the part of the blank which is directly under the electrodes, and very near to the edges of the electrodes, that determine the frequency. I was close to some 135 MHz crystal filter some years ago, but wasn not aware of the technology useed -- it wasn't used in the final design.

==========
In the Netherlands and probably other EU countries all electrical goods are subjected to a 'disposal fee' related to the purchase price and size/hardware content ,which is to be paid upon purchase.

For a hair dryer the fee is low , for a TV set or laundry machine the fee is much higher. Old /defective goods can be returned to the shop the goods were purchased ,or to the relevant municipal waste depot.

Good system where money is paid up front to pay for eventual disposal/ recycling.

One of the early 'top' recycling countries in Europe is Switzerland.

Yes indeed . A few years ago I saw a TV programme on lead acid batteries
recycling.
Used batteries were shipped from the USA (back)to Taiwan,with the lead
being recovered there . A dreadful operation. Working conditions and
resulting pollution of the local environment were really bad.

And the electronics shops are supposed to return a certain amount of
rubbish for the consumer electronics they sell. If they can't provide
this they must pay a fee. Some shops collected the old PC's to give to
schools in Poland, but had to give up this practice because it reduced
their rubbish to be collected

On the other hand they might be pleased to solve your problem to get
rid of your rubbish

Source record: 23592

I'm interested in building something to allow me to monitor the backup battery voltage on our local repeater. I was thinking of using some CAT-1000 user input leads to be activated depending on the battery voltage. I could probably use some comparators and logic to allow only one lead to be active, depending on the battery voltage and then use that to activate a macro to 'say' the actual voltage. Anyway, I was wondering if anyone had any thoughts on the idea and if maybe someone already created such an animal.

A microcontroller with an ADC would be the best way. I'd use the PIC 12F675
and output the voltage in Morse.

Plessey emitter-coupled logic, like MECL, which is made by Motorola.

Real sensible question.
```

Just like the one about two white guys and a black guy
arriving at Heaven. St. Peter asks the first guy what famous ship was
sunk by an iceberg. Guy answers, "Titanic" and St. Peter waves him in.
St. Peter asks the second white guy how many died. Guy says, "1503"
and St Peter waves him in. Then he turns to the black guy and says,
"Name them."

Many people don't realize that most of the high tech parts of
electronics equipment, such as the, ahem, CRTs, are _made_ right here in
the U.S. and shipped to another country for assembly. Sony's San Diego
plant is one notable example.

Disagree.

>Your tracking will be messed up

Agree. Sensitivity will suffer at one end of the dial.

>and alignment with an oscilloscope needed.

Disagree. Just your ears will do.

Assuming we're talking the old style dial tuners, and not digitally tuned receivers, it's possible to get them to recieve up to 1.8 or 1.9 MHz. You can sometimes hear AM b/cast stations above 1.6 MHz and amateur radio 160m activity (some of which is AM) above 1.8 MHz.

Details at http//www.alphalink.com.au/~parkerp/160.htm

At one time I fiddled with an FM clock radio and could hear ambulance or police around 80 MHz. The bandwidth was dreadful, signals blotted each other out and you had to crank up the vol control due to the low deviations used (relative to b/cast WB FM).

Ahh - the good old days!!! I remember putting 10pF ceramic caps across the
FM side of the tuning cap in an old AM/FM clock radio, then listening to the
local police on 83-84 MHz. Worked well if you turned up the volume and, as
you say, had some separation between the freq's you wanted to listen to.

Cheers

Allen -

I am very aware of the surplus stores that are mail order and that have store fronts in various parts of the US (e.g. MECI - Dayton; Fair Radio - Lima; tons in California).

I visit the Northern NJ area on a regular basis and wondered if any surplus operation (walk-in) existed since the area I pointed out is next to Fort Monmouth - which has grown over past 10 years -- and was largely radio and communications oriented when I toured it in mid-1990s. This area is also former mfg. location for EAC (division of Hammerlund) that built the R-290A receiver during the Vietnam war era and several RCA and Bell Labs/Lucent facilities were scattered from this area to the Easton/Allentown, PA area.

My first though is that any surplus operation has closed - in favor of tourist ventures associated with "Jersey Shore" -- but I asked.

PECL is ECL run from a positive supply. ECL is normally run from a negative
supply respect to ground. So, they have the sme swings, but different "bias"
levels.

PECL = positive-supply ECL. It's set up to run from a +5V supply
(with the metal case grounded), instead of the usual -5.2V for ECL.
Has nothing to do with Plessey.

I believe it's spec'd +/-20ppm total from -40C to +85C. It uses a
standard AT-cut crystal, I believe, so one could find a zero-slope
operating temperature and it'd be quite stable.

Cheers,
Tom

Yes, you are correct. Plessey used to make it. Please excuse my confusion.

2224. Good Cheap Soldering Iron

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-09-03 19:13:00 UTC
From: Tim Wescott <tim@wescottnospamdesign.com>
Message-ID: <10jhghqd88iv41f@corp.supernews.com>
Source record: 23508
Cross-posted to: rec.radio.amateur.homebrew,sci.electronics.design

A friend of mine is putting together a middle-school electronics lab, and wants to get some good cheap soldering irons. I've been traumatized by some really pitiful soldering irons so I don't just want to go price shopping. However, since I've been using professional grade, temperature controlled irons almost exclusively for years I can't recommend any good cheap ones.

Can anyone recommend a soldering iron that will actually work but doesn't cost much? I'm thinking of a rough equivalent to the Weller WP-25, but that costs less than $20 a pop.

Thanks in advance.

Could someone explain how to make a high voltage (10KV at least)
variable tuning cap out of printed circuit board material, or point
me to a site that explains it?

Tnx!

You can BUY tuners that cover other bands really cheap. Just like TV tuners
but cover other bands too. Sharp makes them and others. about $30 a pop.

Tim -

The Weller TCP series is routinely available surplus and easy to repair.

I see WTCPL, WTCPN & WTCPS systems selling on eBay for $ 25 or less --
I have seen in last 4 weeks at Chicago area hamfests -- very good WTCPS &
WTCPN stations selling for
$ 20 to $ 25 (some may lack the stand - but that is an easy fix/purchase)

The WTCPT (current production model) will usually get a few more dollars
depending upon condition.

Used bases run around $5, sometimes $ 10 for a cosmetic excellent condition
unit.

Factory and manufacturing closeouts also produce large number of soldering
stations in this price range.

New in this price range - you are left with a variety of 120 VAC stick irons
of various wattages.

My first "short wave" receiver was an AM radio (550-1600 kHz). An article in pop electronics or somewhere gave instructions for making two coils to put in parallel with the existing ones (RF & OSC) to raise the frequency up to, I think, the 80 meter range, as I recall. Of course, AM was big then.

Salvage sales? A lot of people at our place took home Weller temp
controlled stations as the labs switched over to Metcal, and I've seen
stacks of Weller irons at salvage places (as companies continue to go
belly-up).

It's been a very long time since I have been over that way. I use to go by Ft. Monmouth every day on my way to Monmouth College, now known as Monmouth University. At the time, which was 1967 - 1970, there was a great surplus store just a block from the entrance to Ft. Monmouth. It was kind of off the the right and up a side street, but it wasn't too hard to find. I bought a fully functional BC-457 for $5 there.

But I digress. Why don't you ask the guys in the Ocean-Monmouth Amateur Radio Club, which has a web page at "http://www.qsl.net/n2mo". I'm sure there must be a email address of someone who can answer your question. If they don't know, then probably no one knows.

Air Variable Capacitor

I need for my homebrew amplifier, a working air variable capacitor: ï¿½

Value:1200 pF;
1000 - 1500 volts (closer to 1500v is better);

sizes
H: 2.75 inches (7 cm)
L: 3.14 inches (8 cm)
W: 5.90 inches (15 cm)

if you have something to offer, please email me:
iz0fmaCUTMEAWAY@CUTMEblusat.com

www.circuitspecialists.com has some that look reasonable, although not
under $20 they are temp controlled [*] and have holders. One is about
$30 and the other about $35.

http://www.circuitspecialists.com/prod.itml/icOid/4230
http://www.circuitspecialists.com/prod.itml/icOid/7307

* it says "adjustable output" so may be open-loop control.

I've purchased from them in the past (and also under their other link
www.web-tronics.com) and they seem reputable. YMMV

Circuit Specialists is a good outfit... been around for a long time
(33 years), and they're in my neighborhood (Mesa, AZ), about 20
minutes away.

About the only place in the Phoenix area to buy **real** parts.

I did not mention the second soldering station that Rich references for 2
reasons,

1.) Its price was outside your $$ limit

2.) This station is obviously an OEM version from same Singapore mfg. that
makes the Haako 936 BUT with a connector change instead of the Amphenol/Tyco
used by Haako and Circuit Specialists name.

I do know that some Haako dealers aware of this unit are upset with this
offering and were planning to talk to their Haako representative.

Lucky you. PDX has a Fry's and a little local outfit, but that doesn't count for real parts. I used to live in the Boston area, 30 minutes away from an Active store -- that was nice, particularly since it backed up against Future (same company) & you could get non-catalog items at the counter if you really needed them.

When I lived in the Boston area Radio Shack was a real parts warehouse
(on Commonwealth Avenue) with a will-call counter (only 45 years ago
;-)

Out of curiosity, why does it have to be out of PCB material?

For voltages 0-5KV, air variables are OK; for 5KV+, vacuum is the only way
to go, IMO.

If the Hakko dealers are upset about Circuit Specialists, they really ought to
"love" Madell Technology Corp. (http://www.madelltech.com). They have a QK936A
station that not only looks exactly like a Hakko 936, it appears to use the same
connectors. They also sell several hot air stations that look amazingly similar
to Hakko units.

Tim -

How many do you need? I have probably 4 or 5 original NOS Weller WTCP
stations (no neon, no switch) - that I have here.

One middle school talked to me about them - but I think they are getting a
donation from a local mfg. company

This iron costs $25 and works well for DIP down to TSSOP. Along with a cheap
larger iron for big wires and a heat gun for desoldering, it's all I use.
Plus holds less heat than a big soldering iron, lessening damage if someone
grabs the wrong end.

Hi Group,

Many thanks to my question about the 100MHz OSC, I did recall I asked about them a few years back. I was back looking at a RF down-converter for my FRG-9600.

This was based on an article in Ham Radio Mag around 84 time frame. I good ham sold me a few of the crystals which have 100 MHz on them and the article has the circuit which should get it up to 100 MHz.

Anyway, I have a few volume controls which need to be cleaned, is there anything over-the-counter which would do the job?

Tnx de KJ4UO

Allied, http://www.alliedelec.com has several variaties as does Mouser,
http://www.mouser.com if you don't have a local real electronics store.

Here in the UK virtually all the local component outlets have disappeared.
However, there are plenty of mail order suppliers and one can get most items
the next day.

Gad, I haven't seen carbon tet for sale in this country for decades. It can seriously damage internal organs and the nervous system, so I wouldn't use the stuff even if you could find some. You can get other, less toxic (although not non-toxic) solvents like toluene or acetone that can do about the same job at paint and DIY stores.

I've had very good luck using WD-40 for the purpose, though. It's a very good solvent, can find its way in through the small gap around a shaft or other places, and leaves a lubricating film on the element. Variable resistor wipers and switch and connector contacts don't seem to have any trouble cutting through the lubricating film to make good contact.

==========
Indeed ,considering all the States side parts stories , in the UK we are
most fortunate in having a number of small, often '0ne or persons '
companies supplying (by 'next day' mail) a large variety of common and
sometimes not so common parts at very reasonable prices.
Because of their limited turnover they are not forced to levy Value Added
Tax (VAT) = purchase tax.

I am a happy customer (only) of the following 2 , but there are many others
:

For this purpose I normally use 'Contact Cleaner' which is non-chlorinated.

A supplier here in the UK is : Maplin who has stores in many cities and
towns in the UK ,even in Scotland .

Good stuff. My old 25W Antex is still going strong after more than 20
years! I'll probably buy one of these 15W jobs for the odd SMDs I use.

I do not believe thet were as upset with this firm, since the rpice discount
was not as deep and supposedly "one-time" OEM deal -- which as everyone sees
know -- was not true.-- I would not be surprised that some Haako dealers
will drop the product.

Remind him to consider the health and safety issues before making
a final decision. In the EC (and perhaps elsewhere) one soon will
only be able to get lead-free solder so the soldering staions will
need to be compatible with this. The fumes from flux also need to
be considered.

The exposure to fumes by a child will likely be minimal but, as
the purpose will be 'educational', there may be a duty to employ
best practice so they end up knowing what a safe workstation is
like.

Since my first electronics job in 1967, I've used all manner of stuff to
clean pots, switches, tuners, etc. Tuner cleaners work, but frequently
a dirty pot has to be recleaned every week or so for a while. The best
stuff I've ever used is DeOxit D5 spray; always works, seldom needs
to be reapplied.

Since the EPA took trichloroethane out of tuner cleaners, none of them
seem to work worth a damn.

I agree fully. Sorry, I didn't intend to recommend any of these solvents for cleaning pots or most other electronic parts -- for the reasons Bill states. Acetone and MEK are also highly flammable and not good to breathe. Carbon tet was a good degreaser -- I remember using it to clean the surface of a balky crystal. The solvents I mentioned are also good degreasers and general solvents, but do attack a lot of materials and need to be used with caution.

Several years ago I was driving, and stopped for the night at a Howard Johnson's. The only room they had available had no TV, so I brought i an AM-FM portable I had in the car.

The radio had spent some time in the sun, and was pretty well 'cooked', you might say.

The FM section didn't work at all; the AM section picked up SWBC quite well; I spent the evening listening between VOA and BBC.

I do NOT reccomend this method! :-)

It's rare here to be able to waltz down to someplace local and get real components, unless you're lucky enough to happen to be by a big store.

And Fry's don't count for parts (although they still have decent test equipment for sale).

Hmm. Depressingly good point. I just hold my breath while soldering
and wash up when I'm done but I really ought to get a hood --
particularly since I'm training my kid to all my bad habits.

At different places where I've worked with a bunch of people soldering
at a long bench, I've seen muffin fans at each workstation to keep the
rosin smoke out of their face.

Good Luck!
Rich

Thanks for the URL!

I first started using it in the late '60s, when the company was still Rocket Chemical. My Colorado duck hunting partner got some from a friend in Oregon -- it wasn't available locally yet. I had an ancient semi-automatic shotgun that would jam from the combination of gun oil, powder residue, and zero-degree temperatures. The discovery of WD-40 was a breakthrough -- it was the only stuff I found that wouldn't result in jamming.

Since then I've used it on everything from door locks to frozen slugs in UHF inductors. I have yet to see anything it'll harm. It's on my short list of Great Inventions of the 20th Century, along with latex paint and plastic drinking straws.

Presumably the Q correlates to the TC's shape factor. You could
measure/easily calculate that from just sweeping a signal source
though the TC and measuring the relevant -3dB and (-50dB) signal
levels with a 'scope?

Hello,
Looking at the schematic, the modification does not look hard to duplicate.
Does anyone know of a source for a "kit", or is this going to be a roll you
own thing. Any advice or suggestions would be greatly appreciated.
Thank you,
Keith Spainhour, KT4XW

Computer muffin fans (12 vdc) are a cheap alternative (which is what is
inside the Haako 493 with a filter in front)

The Haako 493 and similiar clone units are available for $ 20 to $ 35 used -
I picked up one for a workbench last month - $ 30 with the shipping !

Train these kids in proper workbench habits and shop safety - first. The
lead-free initaitve is real and in the US we will be working with a "mixed
environment" (repair of older equipment with compnents that may not be able
to handle high temperatures (70 to 90 degrees higher depending upon
formulation used) required for lead-free solders.

Kester has a major training effort underway - just for lead-free
http://www.kester.com/en-us/index.aspx

It's more like 15 to 20 degrees C higher for lead free solder.

I was referencing F, you are quoting C. I think you math is a bit low for C
(63/37 eutectic is 183 degrees C and Tin/Silver and Tin/Copper eutectics are
at 221 and 227.
Here is the solder alloy temperature chart (Kester's) - so everyone can see
the various formulations, as well as pure tin melting point and the
lead-free formulations.

But if you had a whole classroom of N children soldering, then
N dispersals scattered over the N children might result in a
fume density of N * N / N which would be no dispersal at all!

Industrial soldering set-ups have a small vacuum pipe mounted on
the iron close to the tip to draw away fumes.

Hi Group,

I picked up a surplus Radio Shack 43-218A wireless intercom. A search on the site says they are either on 200KHz, 230KHz or 270KHz depends on the switch setting A,B, or C.

I am considering modifing them so that I can put the HF rig audio into one of the them and be able to listen to the rig while in other areas of the house. Has anyone done this? Comments?

I would also like to understand how the 200KHz is inserted on to the power line, does anyone have a schematic of these or similar units?

Tnx de KJ4UO

My first serious soldering was a Knight-Kit at age 14, and I started working full-time as a TV serviceman at age 16. I'm here to tell you that the fumes haven't affected my cheese. Watch it, spaceman, you're crushing my petunias. Nerts. Hot solder pie with crunchy plumbing, yum. No ill effects whatever.

Hi guys,

Still reeling from the screw-up Chris Bowick made of his explanation
of FET biasing, I've come across this little gem which purports to
show the design considerations for a FET amplifier stage which takes
into account the spread of parameters one encounters with FETs:

http://ampdesigns.tripod.com/solved_problems.htm

"Solved problems"? I don't think so. I'm up to six glaring errors
already, but I'm sure there are more yet to be found. How many can
you spot?

==========
I have such a intercom set as well. Upon transmission the built-in
loudspeaker of the 'that time' transmitter serves as a microphone.
Suggest you connect a small 1:1 or about audio transformer across that
loudspeaker . The other transformer winding can then be connected to the
output of the the HF receiver , perhaps with a 10 Ohms resistor across it.
The transformer provides safe galvanic separation .
In addition to the fixed resistor you can fit a parallel say 20 -50 Ohm
potmeter to adjust input signal to the transformer and hence to the
loudspeaker type microphone of the intercom -transmitter. During that type
of duty the intercom microphone might also act as a low level output
loudspeaker of the HF receiver output signal.
If accidentally the intercom 'transmitter ' is set to receive , the HF
receiver audio output stage won't get damaged.

The audio transformer is not critical . I can imagine you can even use a
small power transformer with 2 separate low voltage windings (it being not a
Hi-fi system). It involves some experimentation ....that's part of the
hobby !

If you don't like the above ,you can always try acoustic coupling between
the 'microphone' and a separate rx loudspeaker. Another experiment !
Amateur Radio can be a lively hands-on hobby.

Hehe! I don't blame you, John. But I should perhaps have made it
clearer that the link I posted has nothing to do with Bowick. It's
coursework by some lecturer at Bombay University.

So are the laws of physics different elsewhere?

How about this joke, maybe it will make things clearer-

Two male priests are fishing with a new female priest recently transferred to their diocese on the shore of a huge lake. It is discovered they left their bait back on shore, and the female priest offers to get it. She calmly steps out of the boat, and walks gently across the water to the shore and picks up the bait without even getting wet.

Before she returns, one priest whispers to the other- "They send us a female priest and she can't even swim."

So there was no connection.

The question was:

> > Name one person who died that can be traced directly to
> > salvaging efforts.
> >
> Real sensible question.

Changing to trying to tell very old and lame jokes does not answer the
question.

Provide one verifiable name of a person that died as a direct result of Salvage
efforts.

I just thought I would follow up on the status. I finally found the time
to dig down to these resistors. A bit of a pain getting to them, but not
horrible. I replaced them all (there were 6 of them in the string) and
now focus is great again.

Found one of the 510 K's had become well over a meg.

Thanks for the great tip on what to check.

I think given that it's only about a year old, it is unlikely to find
one used. People are not going to spend the money, and then turn around
and sell it at a loss.

But, given that I have come across some nice books on the used market,
one can never be absolutely certain.

2304. Amplifier Oscillation

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-09-07 13:16:35 UTC
From: Chris <REMOVEchris1379ME@bigfoot.com>
Message-ID: <Twi%c.9583$w%6.6886@newsread1.news.pas.earthlink.net>
Source record: 23487

I have 2 amplifiers with similar problems. One is an EB63 kit (http://www.communication-concepts.com/eb63.htm) with MRF455's. The other is an old broadband "brick" with MRF450a's. They operate normally into a dummy load. The problems start when connected to an antenna. At low output levels, there are multiple frequencies present. It's not just harmonics. At 28 MHz, there is a very clear .5 to 2 MHz component visible on the oscilloscope. On the power/SWR meter, it looks like a high SWR and incorrectly high power reading. When the output power of the amp gets close to max, the oscillations disappear. The scope trace, power, and SWR readings are normal. This happens on several mobile antennas and an inverted V so I can't blame the antenna or cable. I also have 3 other amps that work perfectly in the same setups. I'll post the scope traces to alt.binaries.pictures.radio if someone wants to look at them. They are also posted at the bottom of http://home.earthlink.net/~cjohnson1379/ . I have tried collector to base feedback and different combinations of capacitors on the input and output sides with little or no change. What about changing the number of turns on the transformers? I hope someone can figure this out because I'm about to go nuts. Thanks so much to anyone who can help.

Chris

You need to decrease the feedback resistor from collector
to base; too much low frequency gain.

It looks salvageable. The quick and cheap way to get operational would
just be to improve the post-PA filtering, but that won't prevent
parasitic oscillation of the PA itself if that's where the fault lies.
The problem may well be a few stages back. I'd try using the 'scope to
check the purity of the pre-PA stages back along the tx chain and see
where exactly the instability arises. Then you'll have a much better
idea how to fix the problem. If your lucky it might just be poor
decoupling at an earlier, low-power stage.

<< They operate normally into a dummy
load. The problems start when connected to an antenna. At low output levels, there are multiple frequencies present. It's not just harmonics. >>

Chris-

I agree with Allison that you should look at the power bus. You often find designs with two or three parallel filter capacitors with values spread over the range of 100 pf to 10 uf, all with shortest possible leads including PCB tracks. As I recall, this was part of the cure for oscillations in the Heathkit 10W Walkie-Talkie amplifier.

Then there is the effect of load impedance (or input impedance on the previous stage) and its relationship to a VSWR protection circuit. With a resistive load, even out-of-band signals are matched, so there is no drive reduction. Therefore you have full power which seems to prevent the other-frequency oscillation from occurring. However, a real-world antenna may be matched at the intended frequency, but not at out-of-band frequencies. The VSWR protection circuit reduces drive, which allows the spurious oscillation to grow, causing more out-of-band signal, reducing drive even further. The result is a complex waveform consisting of intermodulation products of the intended signal and the spurious signal(s). This effect would be more likely to occur where drive reduction is accomplished before the stage that is oscillating.

Although not a cure, you might try defeating any VSWR protection circuit in either the driver or the amplifier, and see if the problem is reduced.

I found an almost identical problem in the old Regency HR-6 and BTL-301 tranceivers. The only thing that actually seemed to cure the problem was to short the emitter lead of the final multiplier stage to ground. I noticed that later versions of the BTL-301 moved the VSWR protection drive reduction from an early stage to a later stage. This made significant improvement, but wasn't a perfect cure.

Source record: 23493

The driving radio is an RCI2950. The radio output goes directly into the input transformer. There is a VSWR of 1.2:1 between the radio and the amp. I also tried adding various caps on the power lines to no avail. As mentioned earlier, I have another amp with MRF455's with no problems. The only big difference I see in the circuits is thatr the good amp has an RC network between the input transformer and the bases.

I had a problem with the 454's. Using all the supplied parts, the output was low and the current draw was high. This was solved by replacing the 910pf cap between the collectors with a smaller value. I never tried it on an antenna then. One of the 454's died because the radio output was too high - my mistake. Once I get the amp working, is there a way to reduce the input to the amp? I've seen some designs with a simple voltge divider. Would that work OK?

Thanks,
Chris

Yes it is, but such a characteristic seems to be totally lost
on most newcomers who are no better than CBers who buy
their complete station off-the-shelf and even send it back to the
dealer for repairs.

Sadly they are misled by the Mongolian hordes of
CBers-Masquerading-As-Radio-Hams who have corrupted
Ham Radio in recent years. (And you don't have to have ever
held a CB licence to qualify for membership of that class
of failures - merely having a station of entirely off-the-shelf
consumer-type purchases puts you fairly and squarely
in that group!)

Thanks alot. I saw one vendor that lists SD1446 as a sub for 454's. I realize they may work for some applications and not others. Will they work here?

| Chris,
|
| That amp was designed around MRF454 not 455 there is a difference
| and the 455 has a tad more gain and different match. I might add the
| MRF454 is a 80W device and the 455 is only 60w as well. The
| differences are not always apparent and the output match and reverse
| transfer are very different. Pull the datasheets for both off the
| 'net and look at them.
|
| The design requires a matched pair. The bias seems to be best
| at around 200-300ma per transistor. Any asymetery in grounding
| (that includes mounting the PCB to the heatsink) can also cause
| problems. The transformers MUST be wound as specified using
| materials as specified.
|
| If you going to try and tame the beast. Try this. From collector to
| base on each transistor: series connect, 12ohms (2w non inductive),
| .33uH molded choke and capacitor pair (10uf and .1uf in parallel).
| the leads for these must be as short as possible (none or nearly so).
| This may work. If not:
|
| Feedback version two: FT50-43 torid with 10t #26 from collector to
| collector, pass through the center a 4.7ohm 1/2watt resistor and
| connect the leads to the bases. If the leads are backward it will
| oscillate in that c ase exchange the leads for the 10turn winding

| between the collectors. If this doesnt work used MRF454s.
|
| If feedback works expect about 1-2db of gain reduction and a
| corosponding increase in required drive for the same output power.
| However, do NOT exceed 5W input power of the transistors will cook.
|
| Also if you scope the power leads at the junction of the output
| transformer and see anything going on there in the below 5mhz range
| you bypassing on the board is wrong or grounding ineffective.
|
| One OBTW: input and output connectors, case and grounds. I've seen
| one that when on the bench open worked as predicted. In the case
| built by the owner it would take off. Seems the case and the SO239s
| mounted to it were RF wise not at the same ground as the groundplane
| of the PCB and created a untidy feedback path.
|
| I've built "EB63", it was featured as an app note from Moto some 20+
| years ago and it was a stable design using the MRF454s. I had little
| trouble with it as a base design for a 18-35mhz commercial
| application.

Thanks for the reply. The EB63 is in a box right now so I'm playing with the other one. The toroid with a resistor seems to help it but a piece of wire all but eliminated it. I don't know the properties of the core but it has the same dimensions and was wound with #20 wire. This amp uses 2 GE 104P1 transistors that I had around here. I think it originally had TRW transistors and an 80 watt output. Is it OK to vary the resistor and number of turns to achieve best results?

Thanks,
Chris

Source record: 23406

I suspect we old-timers are wrong in believing that more radios were designed or made in the past than today, probably by factors of 500% or more. The main reason is QRP radios using modern ICs for the receivers and MOSFET transmitters, coupled with a revival of nostalgia tube simple transmitters.

Our campus radio club W5YF is building several pixie-2 cw transceivers ($10 kits from HSC) as a project for newcomers. As part of an IEEE construction and kit building event tonight, they are offering free SWL radio kits, free robotic kits to students to encourage them to build electronics skills, learn to solder, etc. We are also building a cross band repeater (for ballooning), an emergency power system, a VLF beacon transmitter (of our own design), and various other antenna projects.

There are lots more people in amateur radio today than in the past too.

Many of the projects built in the past were slavish copies from articles in QST or the Handbooks (ARRL, RSGB..), since relatively few could design Pi networks etc. Today, software makes it easy to customize a design to parts available cheaply, making many designs "originals" ;-)

The cost of constructed electronics, esp. with SMC, has dropped (along with low cost labor etc.) such that kits like heathkit are more costly to build than to buy, due to need to write instructions manuals etc. ;-(

Lots more information is available online too, making it possible to do things with surplus "junque" that we couldn't before due to lack of specs or pinouts etc. Similarly, lots more projects are being built from online articles of other folks successful projects.

EBay has made huge amounts of surplus test equipment available, moving it from inactive users to those having a need for such items, and reducing the cost of electronics construction. At our local sidewalk sale last weekend (http://people.smu.edu/arc/sidewalk.html), I picked up a large working VTVM that also did RMS volts and resistance and even capacitance from pfs to 2,000 uF, as well as 4,000 volt scale volts - for $5, 8 digit counter and display with reset for $1, and a computer UPS with 12v SLA for $3. I can't build an SLA battery charger for that, or a capacitance meter, so one reason some folks aren't building is that buying used or online is much more cost effective, plus provides extra features (e.g., a VTVM+, a 300 watt sine wave inverter etc.).

One interesting argument put forth by Forest Mims III (pop tronics author, in Nuts and VOlts magazine recently) is that we are no longer component level builders, but rather system level designers. So I'm designing a cross band repeater with CW-IDer, beacon DF transmitter, and possibly ATV

transmitter for our club's 75th anniversary high altitude balloon project. The CW-IDER (from K1EL) is a single chip microcontroller which not only does the whole morse code ID message generation, including sidetones (for 7 messages ;-), but also does the 10 minute (0 to 600 second delay) timer for the repeater - for $8, preprogrammed, including mailing. What would have been a major project (CW-IDer for VLF beacon and balloon project) is now a single component and ten minute ordering form away. ;-) Sure, I could build one from an EPROM and logic and timers - but not for $8. Should I feel bad I'm not doing discrete logic work again, or be happy I can focus on creating other functionality in the system? Hmmm? ;-)

Similarly, many radios are rather complete today, unlike in the past. You needed to have an outboard audio filter with some rigs, today, DSPs are built in. You needed a VHF SWR meter, now some rigs have these built-in, along with lots of other functions. So the need to design and build has been decreased as the complexity of equipment has increased. The cost of a used 2m handheld radio (often $50 even for an older synthesized rig) is so low that you can hardly build such a complex item except to say you did so.

On the other hand, I think there is a lot more interest and construction where it does count, e.g., building antennas, as the rec.radio.antennas group suggests.

So I think we should be happy that modern technology has eliminated the need to build needed "accessories" to our main radios, which now include such needed features (and many others ;-). We also don't have to build from the ground up, since used gear offers a lower cost starting point to building a station. On the other hand, many ham stations today are much more complex than in the past. Most of us run HF and VHF/UHF, many do multiple modes, including digital modes, and work specialty areas (like ATV or satellites). Our focus is not on building a single radio transmitter, rather we are focusing on expanding our radio station capabilities in modes and bands and facilities (including emergency power..).

my $.02 ;-)

I'm sure you're right. But AFAIC, I prefer doing things from the
ground up. That way, you learn a hell of a lot more. I'll stick with
my discretes and continue to make 'em work at RF., for all hassle,
they make life infuriating but *so* much more challenging. Perhaps I
should get a better psychiatrist. :-)

Or it's really too much? >>

Tony-

I didn't see your previous posts. Yes, you should be able to modify the tuner, but it means replacing the front-end tuned circuit as well as the local oscillator's tuned circuits.

Another approach is to add a converter stage between the 4000khz antenna and the antenna input connector of the tuner. Such a converter might have a 4000khz preamplifier stage, a converter stage and a local oscillator stage. If the local oscillator were crystal controlled, you might be able to tune the frequency on the AM dial, with frequency determined by adding a constant.

This is the best approach. It's best to use an AM car radio that has analogue tuning for this sort of thing. A crystal for 5 MHz would be OK - 4 MHz would come up at 1000 kHz on the dial.

An excellent project is a converter using 4 & 5 MHz crystals and a tunable front end. This will give you a receiver that tunes continuously between 3.5 and 7.5 MHz in 4 bands. You will need a double tuned circuit at the front end to resonate over this range. Add a 455 kHz BFO for SSB.

This is a pointless question.

Any hobby can be made as technical or non-technical as its adherant wants.
None is necessarily superior to any other if that's what you were getting
at.

And what is your definition of 'succeeding at'?

What do you expect to hear with an AM tuner in say 3000-4000 kHz
range? There is very few AM transmissions.

In addition you would need a beat frequency oscillator, to make sense
of at least some of the transmissions.

I too would encourage the converter approach.
As to what there is to hear- this is the tropical AM broadcast band and some
of the rarest catches are located here, although I think I would prefer a
radio with a bit more sophistication.

Peter-

With high-side injection wouldn't the dial tune backwards? 4000khz would appear at 1000khz, but 4500kHz would appear at 500khz on the dial.

If Tony can adjust to the backwards dial, I agree that a 5000khz converter crystal would be the better choice, since it might be easier to filter out images at 6000khz than images at 2000khz when using a 3000khz crystal.

There have always been technical hobbies, astronomy, amateur radio, rocketry, home machine shop, and even aircraft building. I'm not sure that it matters so much which is most technical, but I suspect many of those hobbies share the problems of amateur radio. We don't think of those other hobbies because they aren't all that visible beyond their circles, which of course is the case for amateur radio, likely even more so in the case fo ham radio as a technical hobby.

In addition to being a technical pursuit, Ham Radio also provides
some self-delusional people the opportunity to make precious
distinctions between themselves and others in order to provide
those self delusionists with a sense of smug superiority. It's just
another of the psychological benefits of participating in the hobby.

Yes it would. But it's no great hardship and improves one's mental maths!

> If Tony can adjust to the backwards dial, I agree that a 5000khz converter
> crystal would be the better choice, since it might be easier to filter out
> images at 6000khz than images at 2000khz when using a 3000khz crystal.

Agreed. I have a h/b receiever that tunes 1.6 to 4.0 MHz as a tunable IF.
There are xtals every 2 MHz in its front end converter. Using a 2 MHz xtal
for the 4-6 MHz range hardly worked at all, and it was better to switch in
the 6 MHz xtal and accept backward tuning.

Another benefit is that 5 MHz xtals seem to be more obtainable than 3 MHz
xtals.

There are some of us "CBer's" who enjoy the equipment as much as or more than the use of it. I definitely won't argue that CB radio is corrupt beyond salvaging. That's why many CBer's turn to ham. I have known many hams who dx on ham bands but use CB to talk to locals. That's how I learned alot of what I know and got interested in amateur radio. I don't have my license yet but I have the resources to study. I just hope that not too many CBer's who want to convert are met by hams who shun them. In one of my other hobbies, R/C aircraft, there are always people willing to spend their evenings and weekends teaching the newbies. The market there is also dominated by ready-made equipment now but if not for the dedicated builders who help others, no one would build there own anymore. One thing is common to both hobbies. The more you do it yourself, the more you learn. For now, it's back to studying.

2349. ALC problems HF radios.

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-09-09 00:23:38 UTC
From: ablight@alphalink.com.au
Message-ID: <1fc7b362.0409081623.4ccbf6f@posting.google.com>
Source record: 23433

Hi All,
I posted a query a few days ago re problems with no ALC on TX on 80m in 2 Yaesu radios - thanks to all who replied, while they were of limited use, it did get my brain thinking about the real peoblem The root cause has been found in one of them (A Yaesu FT707) and was caused by the "golden screwdriver" of a previous owner.

Setting up power output level as per the manual corrected the problem - when power output was taken back to 110 watts, the ALC started working!. The ALC did work on 40m and above, I suspect the sensitivity of the directional coupler used to monitor ALC was less at the lower frequency.

The mechanism is thus - power output is controlled by adjusting the level the ALC cuts in - if you crank it up to max power then the ALC amplifier cant generate enough voltage to limit transmitter drive - you wind up with lots more power out, but effectively no protection of the output transistors - the alc circuit also controls the thermal operation point of the cooling fan, and also provides high VSWR protection.

The moral of this story - a fault aint necessarily complex, just stupid!.

Hope this helps sme other people. Still have the FT747 to look at, but suspect the same sort of problem - complicated by not having a service manual for this one, so will have to poke around till I find the relevant adjustment points.

actually, I would suggest that ham radio is the MOST visible technical hobby, esp. lately, at least here in the USA. The recent spate of hurricanes in florida has highlighted the role of amateur radio during such communications down events. The Sept. 11th (9/11) terrorist attack video programs are playing now on PBS, and the crucial role of amateur radio during the loss of communications seems to get cited a lot too. The recent video on the web (cited in radionews latest issue IIRC) is another example drawing amateur radio to the attention of millions.

Amateur radio's profile on our campus took a big jump after 9/11 too, as we are now increasingly an integral part of our new campus emergency communications program, with a new emergency powered UHF repeater project underway as I write this for this semester.

Now astronomy, for that we head out to dark skies as far away from other people and lights as possible - now that's a nearly invisible technical hobby ;-) Only a relative handful of people build their own planes, vs. 650,000 hams in the USA alone. About the closest group to beating us in public visibility is probably those guys and gals with the battling robots with buzz saws on PBS robot wars, right? ;-) ;-)

see http://www.dxing.com/tuning.htm for what is on various SWL freq.
segments and bands, including the 3-4 Mhz segment...

I just gave a talk on SWLing as an entry to amateur radio for our club:
see http://people.smu.edu/arc/swlfun.doc for handout
see http://people.smu.edu/arc/swlfun.ppt for talk powerpoint slides
*see http://people.smu.edu/arc/shortwave.html SWL radios for future hams

depending on your goals, you may find the comparison(*) of $50 spent on a
kit shortwave radio (ramsey SR-1 2 Mhz AM only kit) vs. degen 1103 digital
dial 0.1-30Mhz AM/SSB/CW radio interesting, esp. if $$ and performance are
important, and your major interest is not homebrewing but SWL listening?

That said, the first thing I ordered after getting the above radio was the
$10 converter kit from Jackson Harbor Press kits for an ELF/VLF (10-300
Khz) including 10 Mhz crystal (For marker, timebase..) to compliment a
VLF beacon transmitter we are designing and building ;-)

I think that you are confusing my wish to preserve Ham
Radio as a technical pursuit with your own mental processes
which you project so well below.

Perhaps it is that you are an unwitting CBer-Masquerading-
As-A-Radio-Ham who is annoyed at being "outed" and which
annoyance results in you revealing the innermost workings
of your psyche as below?

It is a very exciting and inspiring thing to continue to
educate yourself in all matters of technology - try it and
you'll find that there is more to Ham Radio than your
own CBisation of it!

I shun CBers who wish to remain as CBers.

They are the death of Ham Radio (A good example
of which is the gangrenous degeneration that is the
M3/CB Fools' Licence scheme in Britland)

I encourage all comers who wish to develop their
technical skills and become _REAL_ Radio Hams.

You live in a uniformly convex Universe (think about it). What stops
everything sliding down the slopes? Oh, I suppose gravity has a
tangential component. There is still a paradox; to obtain convexity, all
masses must be negative. So the normal component of gravity should be
repulsive. Maybe everything is ferromagnetic to compensate?

Yes Chris, you're correct, similar situation for myself and some of the kids on the block years ago.

Just show up at the 'airstrip' and one of the old timers would be more then happy to take up your new plane for the maiden voyage, give it a going over and then hand the r/c box over to you and let you learn by doing. Soon we all were flying on our own and teaching the new kids.

Our neighbor was retired engineer with Grumman, noticed we had in interest in model rockets and r/c planes, he could not build himself anymore due to arthritis
but he taught all of us everything he could in the short time he had left.

That was a long time ago but all of us young pups ended up working for Boeing and Northrup. Otherwise we would have ended up in trouble !

Yes, as yet. But given time, no doubt there'll be a category for
autonymous fighting robots. A few of us have attempted it, but only
scratched the surface of the possibilities.

If you're trying to "preserve Ham Radio as a technical pursuit,"
you won't do it by belittling other's contributions to the hobby.
You will however reinforce other's belief that you're just another
grouchy, old, British crackpot who is constantly getting exercised
over what other people consider trivial matters. On the antenna
newsgroup, there's another Briton like yourself who thinks it's of
the utmost importance that hams change the name of their SWR meters
to "transmitter loading indicators." I expect some day to hear of
some Englishman who wants to change the name "spoon" to "pie-hole
insertion device."

Scollay Square was a little before my time.

Of historical note, the Sears Crescent Building there, still standing,
was where A G Bell and Watson worked on inventing the telephone.

Greater Boston still has You-Blew-It Electronics in Needham. (Actually
You-Do-It). A few other suppliers, but not like when this was a center
of manufacturing.

I haven't belittled anybody's contribution to anything.

Ham Radio is a technical pursuit.

CB Radio is a hobby.

CBers and CBers-Masquerading-As-Radio-Hams contribute
to the hobby of CB and not to the technical pursuit that is Ham Radio.

Those who are not technically motivated nor technically qualified
are unsuitable as Ham Radio licensees.

Your resorting to rather silly and childish broadcasting (CB)
in your infantile outbursts below would seem to confirm that
you are a CBer.

Ham Radio has traditions of international gentlemanly conduct
which seem to be lost on you.

Sic transit gloria Mundi.

This is a "homebrew" NG for _REAL_ Radio Hams. I fear that
you and your rants are somewhat out of place herein.

> tracks.

This can be an issue as well. When a cap is above its parallel resonant freq., it looks inductive and can resonate with one of the other caps. A parallel resonance has a higher impedance than the cap. While this resonance may be of poor quality, the extremely low impedance of the transistor collector makes an ohm or two rather significant. Our standard practice was to place a small bead between the caps. They were about 1/8 inch in dia and had about 50 ohms real Z above a few Mhz. This helped to destroy any higher freq resonances while preserving the low freq impedance of the parallel caps.

In earlier days, on VHF, we would sometimes put a "banana" from base to collector. This was our slang for a series orange drop (I think mylar) cap and two (one on each end) low valued resistors. Don't remember all the values, but the idea was to kill the low freq gain. The cap blocked the collector voltage and had enough inductance and in combo with the two (I think 33 ohm) resistors was high relative to the base and collector impedances. I think the cap may have been .01, but memory faded... The low freq collector load in this situation is the supply bypass method...or the power supply leads, in lew thereof....

Heck. I remember running a Development Engineernig prototype 100W Micor on 30 Mhz for many months, wondering why I seemed to have battery problems, when I found large (size -wattage) and quite low valued resistors directly from base to collector of the finals (which were always tied to the battery). Guess someone was trying a flight fix and didn't think any DC blocking was necessary! Transmitter worked fine. I just had a high static drain.

Hi.

Does Tayloe detector work for undersampling of IF signals ? I have a signal of 45Mhz that I want to "translate" to baseband, sample it and take I and Q for processing.

Thanks

Hern&#65533;n S&#65533;nchez

IIRC, Bob McGwier n4ny@amsat.org has done this for the 144 MHz band. This was as part of a Gerald Youngblood software defined radio. Bob said that (of course) losses were greater.

I have some more surplus stuff.

50 pcs 2N2907 PNP transistors (TO92 Plastics)
General Purpose Amplifier/Switch require collector currents up to 500mA
Hfe Max is 300 - I think these were made to compliment the NPN 2N2222
but I am not sure.

These differ from the 2N3906 in that they have a higher current rating for
continuous collector current. The 2N3906 is maxed at 200mA and this
2N2907 is maxed at 800mA.

Other than that, they appear to be the same. The 2N2907 looks like it
is just a smidge tougher on the current handling abilities.

50 pcs 1N4007 General Purpose Rectifier (1000V 1A) 1V FWD DROP at 1A

Total of 100 pcs for $5.00 and 2 stamps. No Paypal this time.

Please include a shipping label.

Actually, it's in I Kings vii.23 and II Chronicles iv.2:

"Also, he made a molten sea of ten cubits from brim to brim, round in compass, and five cubits the height thereof; and a line of thirty cubits did compass it round about."

In _A History of Pi_ by Petr Beckmann, the author states (p. 174) that "There is a story about some American legislature having considered a bill to legislate, for religious reasons, the biblical value of pi = 3. I have found no confirmation of this story; very probably it grew out of an episode that actually took place in the State Legislature of Indiana in 1897." He describes the incident. . .

A bill was introduced in the Indiana House in 1897 which said in the preamble:

"A bill for an act introducing a new mathematical truth and offered as a contribution to education to be used only by the State of Indiana free of cost by paying any royalties whatever on the same, provided it is accepted and adopted by the official action of the legislature in 1897."

In Section 1, the value of pi is effectively declared to be about 9.2. In Section 2, it's said to be exactly 3.2. The bill was referred ["perhaps symbolically", muses Beckmann] to the House Committee on Swamp Lands, which passed it to the Committee of Education, which reported it back to the House "with recommendation that said bill do pass." On Feb. 5, 1897, the Indiana House passed it unanimously.

A charitable person would speculate that, like our current legislators and the more recent Patriot Act, they just didn't trouble themselves to read it before voting.

It was saved from passage by the Senate by the intervention of a Purdue math professor named Waldo who, horrified when learning about it, coached the senators.

History repeats itself. Now political interests are being used to modify, distort, ignore, and contradict scientific findings. And Kansas is once again attempting to legislate against the teaching of evolution. Some things never change.

I'm not sure if you read above but what I did worked on the small amp. I took a core with 10 turns of #20 wire and put it between the collectors. There is a solid piece of wire running through the center of it from base to base. While it seems like this should short something, it worked. The gain is reduced but I get about 60 watts with 4 watts drive. This is an 80 watt amp and it does hit that with a little more input. There is also an attenuator circuit in the front of this one so that's where part of the gain goes. I guess my question is can I hurt anything this way?

I think when everybody gets that smart, we'll all realize that Enlightened
Self-Interest is the best all around. We'll use something much like
democracy for decisions that affect groups of people, like, where should
the road go? Of course, if people would just quit spending on war, there'd
be enough left over to feed everyone on the planet for the rest of their
life, and government would be kinda moot.

Yeah, dream on. Think I'll have another toke. %-}

Cheers!
Rich

2381. Re: Is ours the most technical hobby in the world?

quoting:
CBers and CBers-Masquerading-As-Radio-Hams contribute
to the hobby of CB and not to the technical pursuit that is Ham Radio.

Those who are not technically motivated nor technically qualified
are unsuitable as Ham Radio licensees.
unquote:

you may be right - in Germany (per your path)?

But here in the USA, the justification for amateur radio spectrum and existence is called PICON - public interest, convenience, or necessity. The goal is communications at the most basic level. Technical pursuits or qualifications are not a core concern of the licensing body (FCC).

You also have to be careful about such issues as "technically qualified", since it requires someone to define who is qualified, what they need to be qualified in, and why ;-)

The USA's licensing body (FCC) has defined a rather basic set of core technical competencies for the entry level licenses, and most advanced countries seem to have similar modest technical standards (the old Soviet system may be an exception etc. where you had to build your own radio station?).

Now flip thru an RSGB or ARRL handbook, and ask yourself how many of the various modes and bands and projects have _you_ done? ;-) I am still doing new stuff (VLF beacons, modulated lasers for field day's 3 modes credit etc.), which means I am certainly not technically qualified in all the areas of ham radio yet ;-) Plus they keep inventing new ones all the time.

in short, if you feel you are "technically competent" in (all of) ham radio, you may not be paying enough attention to all that's going on. ;-)

Finally, when the chips are down and ham radio has to prove its value thru emergency communications or whatever, there are lots of very technically competent folks who aren't setup or interested or trained in providing such communications. So the laurels often go to those who some might deride as "appliance operators" who are able to provide such communications. Many of those folks are just as elite and capable in their own areas of ham radio as those with a more technical bent might be in ours...

Wife and I have traveled to over half the states now and we usually try to visit the state capital buildings. (We live 90 miles from the AZ building but haven't seen it).

Most of these examples of sparing no expense when you have an unlimited supply of tax money, try to mimic the US Capital. Some even like to claim that they are taller, wide, grander, etc. They are also very much like airports, in that they are always undergoing remodeling.

One other thing they seem to have in common is an appreciation of the female form, particularly exposed breasts. Mind you, I find these very interesting too, but often the legislators, who during their deliberations are being overseen by paintings and statues featuring these delightful forms, are busy passing laws against topless dancing, declaring "low-rise" jeans illegal, fussing about dirty movies and so forth.

Maybe we were better off under King George, and I don't mean the one currently in the White House.

answer: roughly half, since that's the USA proportion who have gotten on the air with their own station, which usually involves system tradeoff studies and system integration issues, if nothing else, antenna building and location, and so on. Not the answer you expected? ;-)

I keep meaning to write an article for QST on A.R.S.E. - amateur radio system engineers (grins), following up on Forest Mims III observation in Nuts and VOlts that electronic hobbyists no longer work much at the component level (thanks largely to microcontrollers and integrated chips (PLAs...). Most of us work at subsystem level in projects (at least in terms of decades past).

On the other hand, the amateur radio systems many of us have are far more complex, with lots more interactions (e.g., software issues, antenna interactions for multi-bands and modes, satellite orbit predictions, and more modes and bands of operation than the 3 or 5 band AM/CW or SSB/CW rigs of the 1950s and 1970s. We have five different types of antenna coax connectors on our dual band ATV system, between two transmitters, beam antennas, preamps, downconverters, and all the rest.

And yeah, I have EE and CSE graduate degrees as well as a systems engineering grad degree; but the reason they pay systems engineers more on average is that making things work together well (hardware, software..) is often far harder than designing or building the components. Read comp.risks digest to see something of what I mean ;-)

And fyi, practically all the designs now are done on computer (from boeing 777 down), and lots of graduating engineers have minimal exposure to building anything either (usually just a simple senior design project, maybe a few kits on the side). There is very little of the cut and try approach often illustrated here ;-)

On the other hand, they may have designed microprocessor cores and tested them in software, which would have been far beyond some of the heroic and epic hardware designs of just 30 years ago (see my serial #186 example of the world's first microcomputer (Intel 4004 from 1972) at http://people.smu.edu/rmonagha/4004.html).

from http://dictionary.reference.com/search?q=robot

A mechanical device that sometimes resembles a human and is capable of performing a variety of often complex human tasks on command or by being programmed in advance.

A machine or device that operates automatically or by remote control.
endquote:

Depends on your definition and viewpoint; sad to say, virtually all the world's working robots in factories bear little resemblance to humans (other than the demo walking robot from Japan, I guess? ;-0)

We had an IEEE sponsored contest to build software for battlefield robots some years ago (late 1980s IIRC?). End up looking like a video game, which is what the students wanted to build anyway. ;-)

I'm recording a 2 hour PBS program on videogame revolution tonight, so I suspect it will be deja vu. However, Tom Clancy, the noted author of Red October etc., made a point when on campus last year that the military is using videogames corp. for training, and that the years of hand-eye coordination training from gaming was a big plus in preparing young men and women to utilize incredibly complex systems with videogame style interfaces.

Personally, I wouldn't _want_ an autonomous battlefield robot without using some human interaction in the loop. No sense making the term "killer software bugs" come true ;-)

The Massachusetts Legislature passed a law requiring trigger locks on
all firearms not in use.

Then someone noticed the antique Revolutionary War flintlock musket
hanging on the wall of the chamber, and they had a trigger lock placed
on that.

Especially amusing if you understand how a flintlock works (hint: a
trigger lock does not prevent it from firing, just makes it more
difficult).

Yes, the flaw in democracy is that we get what we collectively deserve.
And that's a scary thought.

I entirely agree. It's rather a simple concept; I tell children about
it. It can be related to religion, agnosticism and moral atheism.

The only requirement is that all parties are clever enough, and patient
enough, to find a solution consistent with ESI. For the really big
problems, we haven't evolved far enough yet.

I don't see what's so elite about buying a black box off a shelf,
connecting it up and shouting into it, as most of them do, when the
other station is distant - regardless of quality of reception. Sure,
black box operators may save the day in the event of an emergency, but
the degree of study, experimentation and practice they have to undergo
to pull it off is minimal at best and demands zero respect, IMV.

In some states (Oregon included, IIRC), pi _is_ legally equal to three
-- at least for the purposes of calculating the number of board feet in
a log, and most likely as an informed decision to make calculation easier.

It is, AIUI, based on an average diameter and allows for the taper of
the log.

Probably -- I suppose if you measure more toward the butt end of the log that'll take care of the 0.14159etc.

I used to know a guy who had worked at a company that made estimator pads for log scalers -- had keys to enter all the parameters, an LCD screen, microprocessor, the whole nine yards. The first time he went to check it with a _real_ log scaler this old coot stepped out of the shack, looked at an entire load of lumber on a truck and said "that's about X board-feet". Kevin spent half an hour measuring and entering and came up with the same number.

Progress. Go figure.

That's how my grandfather on my mother's side made his fortune.

At age 17 (in 1913) he was sent by a building contractor to pick up
some lumber (by horse-drawn wagon).

He argued with the estimator that the load was short. (Doing all the
calculations in his head.)

The saw-mill boss came up to settle the dispute... the estimator was
fired and my grandfather was hired.

Later he owned the saw-mill and a coal mine and a *HUGE* farm in
Barbour County, WV.

I am afraid that you are mistaken, and once again it
is your own personality defects that shine through.
I do not look down upon anybody.

CBers and CBers-Masquerading-As-Radio-Hams
are merely following a different pursuit to that which I follow,
as, indeed, are fishermen, needleworkers, football
players and supports, and RC model exponents.

They are merely fellow humans who do not share my interests
and so I do not associate with them.

That you once again resort to rather silly and childish forms
of self-expression below reinforces the perception that
you are a CBer and not a Radio Ham.

Ham Radio is what Hams do, and not what the regulatory
powers seek to restrict.

Radio Hams are technical people. Those who buy radios
off-the-shelf, notwithstanding that they may have qualified
as Hams are behaving as CBers and are viewed as such.

"I know you are a logger, sir, and not a common bum,
'Cause no one but a logger stirs his coffee with his thumb."

Maybe the reason for the rounding down is more obvious than that!

Not always.

Some get enough experience that they can eye something to an amazing
degree of accuracy. Just takes 25 years of practice.

Happy trails,

I only have a link to this one.
http://www.cuuav.org/

There are already soccer playing robots in development (and playing games in
competition) at some universities. You obviously don't watch TV's NOVA.

I couldn't read it all. I was just providing general information.. Without
time and the schematic, I won't speculate...much.

I don't fully understand. A wire from base to base with a coil around it?
Can't picture this and make technical sense of it.

If they are in push pull, this sounds problematic. Doing something that
"works" but has no sound reasoning behind it is not good. I tried to give
the reasoning behind the techniques I mentioned.

>
>Some snipped to save space

Bob, a very well reasoned and written response to the original posting
- I can only concur. What seems to be forgotten is that amateur radio
has only ever been a hobby appealing to a small minority of
technically inclined people - the same numbers are still there, but
with the ready availability of store bought radios, the numbers seem
even smaller. A cursory search of the net reveals many people doing
many interesting things.

If we keep canning each other with "Yor only a CBer" type labels, then
yes indeed, things are grim - things will NEVER be as good as the "old
days" -thats why we call it nostalgia, and your points about using
surplus ww2 junk etc are correct - that wasnt homebrew, it was
adaption of existing equipment.

There is SO much stuff out there that can be modified/adapted to ham
use - junked computer UPS supplies provide a BIG 18v power transformer
for a homebrew linear supply, ex computer switchmode supplies are easy
to mod to 12v at 20 amps plus.

Perhaps the problem is lack of lateral thinking - one thing is for
sure, as long as we continue to argue and bitch and denigrate amongst
ourselves, how can we expect (or even deserve) continued free access
to the radio spectrum we are licensed to use!

73 de VK3BFA Andrew.

After building and molding a pattern, I can estimate how much metal it'll need to within a half pound. That means at worst, a slightly short pour and at most, a bit of metal left in the furnace (which pulls out nicely later). (Check the metalworking part of my website for terms...)

Does anyone know a common part number for the RM3 MOSFET transistor used in RM amps (http://www.rmitaly.com/) like the KL-203, KL-60, and KL-40? I don't need to replace one I'm just very curious. I know it has to be a cheap common transistor.

Thanks,
Chris

And how technical does one need to be? Enough practical experience to screw up a PL259 correctly? (Note I said correctly and by screw up do not mean fettle.)
Enough to know the nature of EM radiation (no heat bands). Enough to understand DSP?

Do tell Gareth. Do tell.

By golly, I guess I must be an old coot. I went to Staples to get a
ream of 11x17 paper. All they had was a box. (10 reams per). The droid
said that was the only way they can sell it. I said, "Don't be stupid.
Just break open the box and get out a ream." This moron says, "Oh, they
don't have barcodes on the single reams, they can't scan it." I just
grumbled at him and went up to the register, and asked the kid, "Can
you do a price check?" - BTW, this was the same kid who had got his
boss, who was the one who said they can't sell one ream. So, the droid
is off somewhere, I go slide a ream out of the box, the kid prices it,
and it's about five bucks. So I go to the droid, and ask, "Are you a
betting man? Tell you what - let's crack that box, and if the ream is
not marked, I'll pay you five bucks, but if it is, you gotta buy it
for me." He didn't want to bet, but he relented, and went and got
the same ream that I had just had scanned, but stealthily put back,
and let me buy it. Maybe this should be a true tale of induhviduals.

Cheers!
Rich

> Rich

I bought a bag of candy at the Ralph's supermarket, and as I checked out the checker couldn't scan it nor find a price on it, so she had to send a boxboy back to check the price. This took a minute, so when she rung it up, instead of 99 cents, she rang 99 items at 1 cent each. I asked her whay, and she said that they are constantly measuring their performance, so if they ring 99 items it looks like they're more productive, like they had to count them out or something like that.

Well, you ask, what does this have to do with the price of tea in China? Well, it gave me an idea. Just go back and get the price off the 2500 sheet carton and divide it by 2500. Then have them ring it up by the sheet(!) They can tell the management that they were extrremely productive and counted them all in only 10.7 minutes! And get a free break, to boot!

I figured it out and a 2500 sheet carton costs $32 so it's $.0128 a sheet. That's $6.40 a ream. But I got the prices off their website and they also show a ream of 11x17 'ledger' as $6.99. So you could save $.59 if they'll do it my way. But their BOFH website wouldn't work without cookies enabled. I'll have to delete them when I'm finished. I think that it's easier to remember 11x17 than it us to remember that it's ledger, plus it's less typing. Same with legal.

Speaking of having fun with the droids, I mailed a package to Tampa Bay, FL, this morning. I asked the postal clerk if he had hurricane insurance for it. He thought that was good for a laugh! ;-)

Depends. Other hobbies that require some serious skills:

Amateur Telescope Making (lets see you design AND TEST multiple optical surfaces with the reqired tolerance).

Home Foundary. Special skills required in safely handling white hot molten metal, and making sand molds.

Amateur Rocketry. (Yup this IS rocket science! Im NOT talking Estes here!)

Home building aircraft. Besides a pilots licence (to test the final product) the skill to do it right (you going to actually FLY that thing YOURSELF!).

Then there was the guy I met in college that built his own SUBMARINE! (he was a scuba diver).

BTW, I AM interrested in numbers 1 and 2, and at one time number 4 (but I havn't flown since my 10 year old kids were born).

2418. Is it possible to modify this radio? kenwood tr-7850

Hi I'm a little new to this news group, have been reading through it for a few only a few weeks. I recently bought a Kenwood tr-7850 at a low price and it works great, but, it would be even better if i could use it to monitor slightly lower frequences used by fire and police. Did a thourough check of the web for out of band mods for this radio and had no success at all. Does anyone have any info on how to do this or a schematic for this radio? Thanks

This was a first generation dual-band (VHF/UHF) synthesized radio. A
general coverage receiver (e.g., aviation frequencies, WX alert channels)
was not in the designer's mind. Nice radio, use it any enjoy it for what it
is. Kenwood's web site should always be your first stop:
http://www.kenwood.net/indexKenwood.cfm?do=SupportFiles

Seems like a new amateur's FAQ is: "How to modify their radio." Must come
from the current "customize your own computer" fad.

Hi w9gb thanks for the info and the quick response. I wasnt aware that this radio was capable of uhf. Not really interested in making dramatic changes and getting the aviation frequencies, mostly just want to extend the low end from 143.900 to a slightly lower ~141Mhz. Research suggests changing programming resistors on the CPU board however it seems impossible without a schematic. There are also about a zillion adjustments inside it and one of them should affect the VCO. So thats why i posted my message, not sure if someone has done this before/has any info or whether i should just forgeddaboutit.

It doesn't make it any more technical. Or dangerous, for that matter.

My goof, this is the VHF radio (2-meter) radio - early 1980s design - I
looked at this model (when new)
http://www.rigpix.com/kenwood/tr7850.htm

but purchased the TR-9130 -- which was the all-mode 2-meter mobile
http://www.rigpix.com/kenwood/tr9130.htm

I have not seen any one both with conversions on this model, of course that
was before this "mod" fad for open up the Far East radios .. meanwhile the
US radios (Motorola, GE) can alreadt do this!

2430. That pesky 7238 kHz CW signal

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-09-12 01:40:35 UTC
From: John Walton <jdwalton@comcast.net>
Message-ID: <Dd6dnWGJXrWdNd7cRVn-gA@comcast.com>
Source record: 23313

From the ARRL's saturday morning missive:

==>"INTRUDER SIGNAL" ON 40 METERS REMAINS A MYSTERY FOR NOW

An unidentified signal that's been showing up on the 40-meter phone band on or about 7238 kHz has mystified amateurs in the western US and Canada, where it's been heard frequently for the past few weeks. Although it resembles a steady carrier, a closer inspection suggests that the intruding signal actually is a series of closely spaced signals. Don Moman, VE6JY, in Edmonton, Alberta, says the signal is quite loud at his QTH.

"This signal looks a lot more interesting than it would sound--just a broad tone/hum/buzz, depending on where you tune," he said. One spectrogram from VE6JY showed perhaps a half-dozen or more discrete signals. "It's certainly loud enough out here, peaking broadly south-southwest from Edmonton," he said. Moman was using a 5-element Yagi and was hearing the signal at 10 dB over S9.

That conforms with observations reported by Bob Gonsett, W6VR, at Communications General Corp (CGC). He says engineers at the CGC lab in Fallbrook, California took a quick look at the intruder September 6 at around 2120 UTC and found "several close-spaced CW carriers--perhaps from one specially modulated transmitter, perhaps from transmitters at different locations," he reported. CGC reported the signals appeared on 7238.063, 7238.150, 7238.237 and 7238.412 kHz, with the 7238.237 kHz signal being "the strongest of the group."

While no one's sure what it is, the FCC HF Direction Finding Facility has been able to determine that it's coming from somewhere north of Prescott, Arizona, and west of Interstate 17. FCC monitoring indicates the "buzz" is centered on 7238.1 kHz with a bandwidth of about 1 kHz and spikes spaced at about 90 Hz apart.

Reports to the International Amateur Radio Union Region 2 Monitoring System indicate the signal has been heard from about 1700 to 2130 UTC, although Moman reported hearing it at around 0300 UTC and said the signal even went off the air for a few seconds while he was listening to it. Jack Roland, KE0VH, in Colorado also heard the signals for a couple of evenings this week. "Something is not right there," he remarked.

High Noon Net Manager Bill Savage, N5FLD, in Albuquerque, New Mexico said several net participants--in Nebraska, Colorado, Nebraska, Wyoming, Minnesota and Arizona--were able to hear the mystery signal.

yes, Andrew, thanks for that note and some very good points...

we recently had our annual regional Hamcom 2004 convention, at which I had the chance to catch local microwave and antennas guru Kent Britain's WA5VJB's seminar on microwaves modifications. My favorite was a obsolete cell phone 3 watt output chip that does 18 watts nicely on 13.8 Vdc ;-) All the wi-fi and garage door conversions into microwave transceivers, and the police radar detectors into microwave setups. And how about some of the simple conversions of TV tuners into spectrum analyzer projects? ;-) And the cable TV modules that do all sorts of jobs from preamps to power amps ;-) So I just joined the North Tx Microwave Society to expand beyond the satellite and ATV stuff we are doing now into new areas for our club ;-)

so thanks to computer and phone co. surplus, we may have a second generation of surplus conversions to rival those of the 1950s and 1960s for military surplus to amateur radio uses?

grins bobm

On the assumption that you would use this equipment once you have upgraded to the Intermediate Licence ,the ATU's power rating is to be in excess of 50 Watts . Perhaps you can state to which type of feeder the AMU (Antenna Matching Unit) is to be connected ; a coax feeder or a balanced feeder.

I'm still searching for another fast and simple solution to push my tuner to 4 o 5 Khz.
What do you think about modifing the local oscillator (whe you found it in the pcb)? Due to high frequencies, it is probably a simple air coil. So I can insert ferrite rod inside it to rise up inductance (and lower the freq)... or i can cut off a spire....
Or modifing the capacitance of the tuning capacitor? I can add another cap in parallel with it, exploing that parallel caps drop down the capacitance...

Hi Craig, I am sure you know you are trying to build a 625 watt power supply. As such, a Linear Power Supply will be large, heavy, not to mention expensive. Unless you have a lot of high volt-amp transformers, 100,000 mfd. Caps as well as big pass transistors with heat sinks in your junk box, this will be expensive. If you do have all this stuff, then use any Linear power supply schematic.
A possibly better soulition would be a Switching Power Supply. These are not easily built because of the difficulity in obtaining the components. Try taking a look at Lambda Power Supplies, and look at Ebay selling Lambda stuff at a good price.

Craig -

The ARRL Handbook has featured a "How To" 28 / 24 volt high current power supply in every ARRL Handbook since 1989 - yes I checked its even in the 2004 version. Mark Wilson, AA2Z built the first one at ARRL labs in 1980s.

Gary makes very good points about linear vs. switching power supplies.

If you wish to build a linear power supply, it is fairly straight forward. You will need a large transformer than has a secondary in the range of 30 to 36 volts AC at 25 amps.

Heat sink design and size (heat transfer of 625 watts - which is not a small issue -- think small kitchen cooking appliances)

Some reference sites for building a linear power supply. You can adopt 13.8 VDC designs by remembering that the voltage is double -- and sizing for current(amperage). The LM723 serves as the "reference voltage" in these designs. A broken power supply (bad transformer) is a great start - case, heat sink, etc.

nope, sorry, but it was a more or less typical example of some of Kent Britain's and others discoveries of easy ways to get onto microwave bands. Raising the voltage on these chips does great things to the power output, as that E^2/R goes up fast as E goes up a little ;-)

Another example was an amplifier with many microwave modules, most of the power was used to produce a linear (digital compatible) output; junk that overhead, and the power went up from 10 watts or so to over 100 watts ;-)

You might try emailing the North Texas Microwave Society or Kent directly? http://www.ntms.org/ - we are having a major conference in October I hope to attend, so I may have more notes there ;-) Kent is also the author of the "cheap yagi" designs from VHF-CQ and other online sources.

sadly, there was a second seminar at Hamcom 2004 on resources for microwave wanna-bees. The first were a series of older books on microwaves and test equipment, with the sensible observation that most of the affordable test gear being surplused now is described in use in these older books ;-) The second was a series of newsletters and publications, some in German/English, from RSGB, and ARRL on microwaves operations etc.

Some of these were described and seen to be quite pricey for the amount of articles therein ;-(The NTMS has evidently made an effort to build up a collection of articles and resources related to microwaves, rather than have each member try to duplicate these costly and hard to find references.

I am not seeing a lot in the way of homebrew microwave construction or conversion articles, given some of the relatively easy projects I have seen described at these seminars and in some ARRL materials I have etc.? So the conference may turn up some more resources, I hope ;-)

Part of the motivation here is we are trying to "inherit" some big roof-top microwave satellite dishes from our engineering school as these get obsoleted as we go online with streaming video on demand. Our club's roof access port is only ten feet from the bigger dish ;-) It will cost the school major $ to take this stuff down, so it would save $ to let us use it - and might provide lots of useful hands-on microwave experience for some of our future graduates. That's my argument, anyway ;-)

If anybody knows of some microwave homebrew resource and project pages, let me know!

regards bobm

There is a 28 volt 10Amp power supply in 2004 ARRL handbook. See
pages 11.36 through 11.39. It should be a simple matter of using a
higher current transformer, rectifier, and additionall 2N3055 pass
transistors for more current, and a minor adjustment of the voltage
adjustment potentiometer to lower the voltage to 24 volts. The
described power supply uses a LM-723 and a LM-317L voltage regulator.
It features current foldback in case the output is shorted.

From other postings it appears that you need a power supply for an ATV
transmitter (repeater?), one should note that ATV transmitters are
usually operated at nearly constant duty (and FM ATV transmitters
additionally at constant load), while typically amateurs transmitters
are operated at (much) less than 50 % duty cycle. I the ATV power
supply, the temperature balance will be reached during each operation
cycle and in the interest of reliable operation, this temperature
should be as low as possible.

Thus, when looking for various designs in the amateur literature,
select one with rated capacity well above the transmitter requirement.
Use larger heat sinks than specified or use a fan. Some
overtemperature protection is also needed, especially if a fan is used
and it fails.

The 24 V 10 A design in the ARRL Handbook is a good starting point. It
uses four 2N3055 series pass transistors, thus 2.5 A/transistor. Even
at full load, the average voltage drop across the transistor could be
8 V, so each individual series pass transistor (and heatsink) is
required to dissipate 20 W. These are quite reasonable figures for the
2N3055.

Upgrading this to 25A should require a larger transformer, capacitor
and rectifier. Ten series pass transistors with larger heatsinks
should keep the individual transistor loading at the same level.The
short circuit measurement resistor value should be reduced.

The worst case current gain for the 2N3055 is specified as 20 @ 4A, so
the total base current for the ten 2N3055 would be well below 1.25 A,
which the single 2N3055 driver could well handle and still assuming
hfe=20, the uA723 would have to supply 63 mA, well within
specifications, however, the power dissipation might be a problem.

Those are worst case specifications for these transistors at larger
currents, but looking at the Motorola 2N3055 transistor, the typical
hfe=50 at 2.5 A at room temperatures or above, thus the total base
current for the ten 2N3055 would be 500 mA and at that current the
single driver 2N3055 will have a hfe > 100 at or above room
temperatures, thus the uA723 would have to supply 5 mA and there would

not be any power dissipation issues.

Of cause, when using typical values (instead of worst case values) to build a one-off project, one should verify by measurement that the typical values apply. This is specially important when "no-name" components are used.

Using larger storage capacitors than specified will reduce the voltage drop during each cycle, thus a slightly lower secondary voltage can be used, which drops the total power dissipation.

It might work, but sensitivity will be poor. As you go up in frequency
band noise drops, so you'll need more gain. Also AM receivers are designed
mainly for strong local signals so might not be particularly sensitive to
start with.

Stick with the converter idea.

The simplest ATU is an L-match. Comprises a coil and a capacitor. Explain that it is useful for matching high-impedence end fed wires approx half wavelength long to 50 ohm and you should pass.

On the SWR meter, the cheapest way you can build something that does a similar job is to build a resistive bridge (check if this is acceptable first). This requires a meter movement a diode or two and a handful of resistors and capacitors. There is no coil winding or toroids. The big benefit of this is that you can tune up without putting a signal to air as you would with an SWR bridge. They are also excellent for low power transmitters as they are more sensitive than many SWR meters (particularly on the lower HF range).

Craig -

Paul and Eric and provided a good background on how to adopt the ARRL
design.
You can substitute the 2N3771 transistor for the common 2N3055 pass
transistor (this is what Astron has done on many of their latest models).

It is not a stupid response at all. Far from it; it is a response that
stands for the maintenance of standards in Ham Radio. The M3/CB
Fools' Licence here in Britland is an advanced CB licence, but it
is not a Ham Radio licence by any stretch of the imagination.

CB Radio is like the cellphone - a social communications facility.

Ham Radio is a technical pursuit.

I note your leaning towards offering violence against those with
whom you disagree. Such behaviour is expected from those who
are CBers or CBers-Masquerading-As-Radio-Hams. It is not
expected from _REAL_ Radio Hams who have traditions of
international gentlemanliness.

This suggestion makes sense for low voltage (5-12 V) high current
power supplies, since the worst case current gain (15) has been
specified for Ic=15 A and in general, the typical current gains are
better at very large currents than with 2N3055. Also the Vbe and
Vce(sat) voltages are lower at similar collector currents, thus, the
capacitor voltage can be slightly lower. From the current handling
point of view, the number of devices could be reduced. However, the
power dissipation would have to be checked, although the junction to
case thermal resistance is smaller, this does not help the heatsink
very much.

However, the ARRL 24 V supply uses only 2.5 A/transistor, so the
current gain and Vbe and Vce(sat) are not really an issue, but the
power dissipation issues are much worse on 24 V than on 12 V. The
power dissipation may still require that ten 2N3771 are used, which
are usually a bit more expensive than ten 2N2055 transistors :-).

Please note that the maximum Vce for 2N3771 is only 40 V and since the
capacitor voltage can exceed 40 V and in case of a short circuit, the
emitter is close to 0 V, the Vce could be exceeded. At least use the
2N3772 for the 24 V supply, since the maximum Vce is 60 V. The 2N3055
is also specified for Vce=60 V.

I suppose it is to be used for a linear amplifier, and then it is a
not a good idea to use stabilized voltage. It might have been needed
for 14V, although Atlas 210-X was operated without - with a varying
voltage between 11-16V, but is not the same problem for 24V.
With maximum voltage of +32V the output may drop down towards 24V, and
no problem at all - apart from setting a limit for the power input

Hi,
I am contemplating a pep reading wattmeter so I can check the output of my HB amplifier. Consequently, I am putting it right on the output of the amp. The output of the amp should always see 50 ohms because it will be feeding either a 50 ohm dummy load, or an ATU tuned to 50 ohms. With that in mind, I am simply using a resistive voltage divider, to get a voltage sample, and squaring it with an AD633 multiplier. This seems like a simple, cheap way to get watt info. assuming you will always be working into a near 50 ohm resistive load. Anyone see any reason why this will not give you a pretty good indication of your power output? I realize that the load may not always be exactly 50 ohms, and that there are losses in the ATU.
The reason I have not tried getting a current sample and using the conventional VI COS Theta with the multiplier is due to the additional complexity of circuitry. It is also difficult to get accurate current samples over a wide frequency range. By making everything resistive it somewhat takes the frequency dependency out of the problem. Thanks.

Apparently this was needed for ATV, however, I have no idea if it was
for AM/VSB-ATV or FM-ATV.

>and then it is a not a good idea to use stabilized voltage.

This is certainly true for tube amplifiers which can tolerate high
standby voltages.

However, especially with bipolar RF transistors, if you first run them
at a lower voltage, high current and high dissipation and thus finally
with a high junction temperature and then reduce the loading, the
power supply voltage is increasing to the standby value, you are going
to have secondary breakdown problems.

When operating with an unregulated power supply, you must make sure
that during idle condition and maximum mains voltage, the storage
capacitor voltage is always less than the maximum allowed Vce for the
RF transistors. However, when loading the amplifier, the power supply
voltage drops 10-30 %, thus the RF output would drop even to one half
of what would otherwise be available from these RF transistors,
assuming adequate heatsinks.

It makes perfectly sense to use cheap series pass regulator
transistors in order to get the maximum power out of the expensive RF
transistors by running them all the time close to the maximum allowed
voltage.

Even if you accept the hum problems associated with unregulated
supplies, at least use some simple series pass regulator to limit the
standby voltage to the maximum allowed for the RF transistors. When
the capacitor voltage is below this maximum, simply put this regulator
into saturation, with less than 1 V drop, thus the amplifier Vcc
follows quite closely the capacitor voltage during discharge. The
dissipation in these series pass transistors would be quite low (low
current at high voltage difference, only the saturation voltage at
high current).

>It might have been needed
>for 14V, although Atlas 210-X was operated without - with a varying
>voltage between 11-16V, but is not the same problem for 24V.
>With maximum voltage of +32V the output may drop down towards 24V, and
>no problem at all - apart from setting a limit for the power input

Only problem that you must use 32 V RF transistors (64 V for collector modulated AM). With a regulated 24 V supply, you could use 24 V (48 V AM) RF-transistors and get the same RF output assuming identical power dissipation and current handling figures. The price for higher voltage transistors is usually higher.

With AM/VSB-ATV this will cause truncation of the sync pulses and possibly hum bars in the received signal (since the receiver a.g.c is derived only from the "constant" amplitude synch pulses :-). On FM-ATV there could be two noise bands across the screen.

Rubbish. I know several M3's, some of whom I have met on air (CW, that is). Proficient and courteous ops. Some of them are enthusiastic homebrewers, whose technical knowledge surely exceeds many, if not most, "full" license holders. To date, every M3 I have met is on his way to the full license. Several have got theirs since I first knew them.

I suspect that the majority of "full" license holders, "real" amateurs you would call them, buy their black box straight after the license arrives and never heat up a soldering iron. So what? If they're interested in ATV, CW, SSB, VHF, UHF, digital modes, homebrewing, DX'ing, whatever - who cares? The aspect is wide enough to cater for everyone's interest! Have your own interest and enjoy the hobby, without needing to mock others who enjoy it in their own way.

For myself, I have never operated a black box rig. Every single QSO I have ever had was on my all-homebrew station, see http://www.hanssummers.com/radio/g0upl/qsl/index.htm. But I still don't care who else does what - they ham their way and I ham mine - I know how I enjoy the hobby and I get on with it. When I CQ anyone is welcome - any speed, country, AND license class! I can't believe that there are those who'll hear an M3 and refuse to answer their call. Is that what amateur radio stands for?

May I also assure non-UK readers that Mr Bean's opinions and attitudes are not representative of UK amateurs in general. Mr Bean does seem an appropriate nickname however.

>

Yes - have a look at my version
http://www.hanssummers.com/radio/atu/atu.htm. I included a 50-ohm 10 Watt
dummy load and forward/reverse power meter. It doesn't read SWR directly, if
you really want to know the SWR then you measure the forward power and the
reverse (reflected) power and put them in the SWR formula.

In practice, 99% of the time you don't care about SWR, you just tune for
minimum reflected power. Operation is very easy - when switched to reflected
power, tune the capacitor to get minimum indicated reflected power. Then try
different L settings by switching the coil tap, and see which setting allows
the reflected power minimum to be deepest. I have a 1W full-scale-deflection
setting for the fine tuning. Then switch to forward power and away you go.

No need to know the actual SWR in practice; the only time I have bothered to
calculate it is when I want to tell people how close to 1:1 I can tune my
various incarnations of longwire antennas. Random length, not cut to any
particular band. Including the bent indoor attic "short"wire I had my first
QSO's on. So far I am very content with my ATU, I have been QRV on 80, 40
and 30m and always found it works well.

I will probably get some flames from this but here it goes. I have been into CB radio for a number of years but don't agree with most of what I hear. That's just one of the reasons I'm looking to amateur radio. One of the things I often hear in CB circles is that one should turn a 4 watt AM radio down to 1 1/2 watts and let it "SWING". How is this possible? What really happens when you do this? I think I know. So, how much carrier should you have for an amp or final stage with a known max output. In other words, if it can produce 8 watts max unmodulated carrier, is a 4 watt carrier ideal? If it produces 100 watts, is 50 watts ideal? How much "space"does it need for proper modulation? Is there a website that explains this well? I'm an electronics tech thirsting for knowledge.

Chris

Many thanks to those of you that have thus far provided me with advice and guidance it is all very much appreciated.

To those persons who appear somewhat offended by the presence of an M3 licence holder - Your comments have been noted and promptly disregarded.

Without the supply of new interested individuals this hobby would eventually cease to exist.

Finally, I would be grateful if anyone could provide me with smoe advice in relation to CW. E.g. Methods available to improve the transmission and understanding CW messages.

Many Thanks once again.

What kind of modulation scheme? Let's assume high-level plate
modulation, which requires the final to be run in Class C (this class
permits the instaneous power output to reach 4 X the unmodulated
carrier when the plate voltage is doubled, as it will be on the peak
of the modulation voltage). The question that
should be asked is if the modulator is capable of delivering enough
power to fully modulate the carrier at the higher power levels.

From what you're describing, they are backing the power back
to properly match a weak modulator.

Pete

>No need to know the actual SWR in practice;

I didn't even have an SWR meter for the first 10 years or so of my ham career. With the link coupled rigs I just shoved the link coil in until the correct plate current was reached (after dipping of course). Same with Pi Net, just adjust for correct plate current. And the war surplus stuff, remember those antenna current meters...

Come to think of it I think I was happier then, ignorance is bliss... ;)

Proper AM Modulation - however it is achieved, should not exceed 100% - lest you sound like CRAP... which is what "many" CBers sound like with their sets modified. Besides, it is against FCC R/Rs to exceed 100% modulation as then it creates splatter to the neighboring channels. An Amplifier on the output will only compound the problem. If you want to talk the world, get into Ham, as you're looking at interest anyhow. Don't waste your time trying to modify some 4 or 12 watt junk to do things they're not really made to do. Besides, with Ham, you'll find out. POWER "isn't" the whole game. Ever hear of QRP? It is working with the least amount of power necessary. Many have worked vast miles with so little RF. Part 97 also calls for working with minimum power necessary. So, there you have it. Also, I've seen cases where those types of mods were more hype than working. If you're really curious, get a good meter such as a Bird 43 and a scope to monitor your modulation, a dummy load so you don't pollute the air with the garbage and another CB to listen to yourself on and experiment with trying to lower the power and up the modulation. Some sets "may" do it, some won't. One other thing - An unmodulated carrier only supplies a portion of the RF. The rest of the power is contained in the modulation. Most amps will tell you the range of RF it takes to get it to maximum output. If you're into CB repair that much, then check out Lou Franklin's book on CB repair. It talks a lot of all aspects of CB repair. Some things I disagree with a little as I've seen some of his theories shot down - but otherwise, a good book. I can't tell you how many golden screw driver jobs I've heard on the air, supposedly tuned as you speak of and well.... they sound like they have a mouth full of shit.

AM 100% modulation is max before distortion of Audio.
The carrier has 50% of the power, the two sidebands have the other 50%.

4 watt is 4 watt, why turn it down, urban rumor
No "space" is needed unless you have a cheap rig.
The carrier will be at 2 watt with 100% modulation.

much of CB is single sideband. Then there is no carrier, and no other
sideband, so you can get 4 time as much, over AM

2482. New Web Forum

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-09-14 21:07:13 UTC
From: microwaves@blueyonder.co.uk
Message-ID: <41485cac.2542425@news.blueyonder.co.uk>
Source record: 23266

The following is the whole text from an email recently sent to be by
Steve Birkhill, G8AKQ, who is perhaps more widely known for his
professional SAT TV work than his amateur radio. He has asked for the
information to be posted widely and so here it is on the newsgroup ...

Peter, G3PHO

.....
.....

Dear All,

For some time now I've been considering the launch of a Web forum
('message
board') specifically for DX enthusiasts, but spanning the wide range
of disciplines this embraces, including radio and TV amateurs,
broadcast engineers and listeners/viewers, satellite enthusiasts,
space communications professionals and radio astronomers.

Today I'm writing and sending this to a short-list of 40 names,
selected either because we're acquainted (or have been in years gone
by) or because of their pre-eminence in one or more of the fields to
which I'm dedicating the forum. This is a one-off, as I'm not in the
spam business, and I hope none of you will consider this an intrusion.

I have set up the categories and boards in the experimental forum to
include at least one in which you might have an interest. In those
where I have any significant personal or professional background, I've
posted an introductory message summarising this.

Naturally, as I'm only launching the forum today, all the content so
far is my own. Please don't let this (either the fact or the content)
put you off! My intention is that this be a place of information
exchange, discussion, debate and argument on anything to do with
electromagnetic wave communication, especially using experimental or
unconventional modes or techniques. Once it develops (if it does) a
momentum of its own (which of course depends on you, the 40 invited
pilot members) I intend to take a back seat and let it run itself. To
this end I will in due course be looking to appoint moderators for the
various boards making up the forum.

To make it work, I need you to visit the Website, browse around,
decide whether it has potential, and perhaps post your own message. If
you intend to post or to start a new thread you must first register as
a member: it needs no more than an e-mail address, which will be held
in strictest confidence. But mainly, if you like what you see, I need
you to tell your colleagues and contacts about the forum and urge them

also to visit. Please feel free to publicise the forum in your column or journal, and place a link on your Website.

Use the forum however you wish, within the broad scope of the 'rules'. You should regard it as flexible: if some of the boards don't work out I'll delete them; if we need to reorganise, I'll do that -- I may have got everything wrong. I have no axe to grind -- it's a totally non-commercial, non-profit venture for the benefit of members. If nobody comes I'll quietly close it all down and do something else. But for now you can find the new forum at:

http://www.dx-forum.com

Just one request: this is a spare-time project for me, a person normally considered as having a negative amount of this quantity. If you all reply to me saying what you think, making suggestions or telling me I'm wasting my time, I just won't be able to cope. At the very least you'll think me rude for not replying. So please, if you have comments or questions post them in the forum itself, for all to see. If it's something specific that needs my input, I'll respond there.

Hope to see you in the DX Forum!

Regards & 73

Stephen J Birkill (G8AKQ), DX Forum administrator

Irrelevant - the M3/CB Fools' Licence is judged by the lowest
standard necessary to obtain one.

Starting from scratch, with a previous irrelevant interest, perhaps
needleworking, fishing or CB Radio, you can obtain an M3/CB
Fools' Licence within 2 days. There is no way that anyone in such
a category has picked up any technical nous to qualify them as a
Radio Ham. If there really are people such as you claim, and you have
not just invented them for the purpose of this discussion, then why haven't
they got a higher grade of licence?

Hans, ask Airy (sorry Gareth) how long he held his licence before getting
to hold a G4.............

Even better, how long it took to learn about fitting
PL259s..... (about 30 years).

Then try: Fixing a FT101 , repairing a TS830, FT221R,
.....

But they have Gareth. Remember your 'friend' the M0 you thought was still a
M3? You know, the one you tried to show how to fit a PL259. Only thing is,
you couldn't fit it yourself. Could you.

He must still be laughing.....we are.

This depends on operator sending and receiving ability. But also important is quality of transmitted note, absence of clicks, slow speed if signals are weak, repetition of important information if signals are weak, use of IF and audio bandpass and notch filters.

Objective: The purpose of the Electronic Design Contest is to promote excellence in the design of electronic systems and help the company to improve circuit design quality by providing competition between graduate and undergraduate students at universities and colleges.

Award: The 1st winner will be grant $100, and the 2nd winner will be grant 10% discount coupon.

Problem: Design DC. motor speed control circuit that is used to control the speed of direct current. Click here for more information (Please don't copy the design from a link.)

Criteria: Submissions are made electronically via the TechnologyKit.us web site. Electronic Design Diagram must be drawn in Microsoft Visio file format. The deadline for submission is October 30, 2004

Check out on www.TechnologyKit.us for more information.

There is no limit to AM modulation, it is not limited to 100 percent
in the positive direction. It is limited to 100 percent in the negative
direction, to prevent cutoff. Positive limits are set by the mdoulation
linearity of the output stage with increasing positive voltage.
Most AM BC broadcasters in this country use assemtrical modulation
for this reason.

Peter

Message-ID: <10kfbffpvnmvcb1@corp.supernews.com>
Source record: 23280

It sounds like a technique I remember calling "controlled carrier". The carrier power was reduced when you weren't talking, then was increased with the audio in an AGC-like manner. Sounded a little weird, but not badly distorted. The objective was to reduce the average dissipation of the final stage, so smaller tubes and a lighter duty power supply could be used.

But I don't see why you'd use a method like this with a low power transmitter, since it's trivial to make one that easily handles the power requirements of standard AM. So I don't really think that's what is meant by "swing". I'd bet good money that whatever "swing" is, it doesn't improve quality or signal strength, and very likely introduces distortion that causes splatter. If the transmitter was designed for 100% modulation of a 4 watt carrier, and you reduce the carrier without a proportional reduction of the audio, you'll be overmodulating and consequently distorting and splattering.

What are the supposed benefits of this "swing"?

Roy Lewallen, W7EL

This coming Sunday....

+++ Now even more Buyers Parking !!!
Thanks to TKT we have use of their new parking lot
across Albany St from the SWAPFEST !!!

!! ** More Buyers PARKING is available ** for details see
http://web.mit.edu/w1gsl/Public/flyer

*** !!!! In our Traditional GARAGE and the adjacent lot !!!! ****
so come rain or shine or super heat the Flea is on !!!

********* $1 buyers discount with hardcopy of this notice ********

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday September 19th 2004
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20 for the first and
$15 for each additional at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,
will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and
W1XM/R-449.725/444.725 (PL 114.8/2A).

Sponsors: MIT Electronics Research Society
MIT UHF Repeater Association (W1XM)
MIT Radio Society (W1MX)
Harvard Wireless Club (W1AF)

For more info / advanced reservations 617 253 3776

news:10kfbffpvnmvcb1@corp.supernews.com...
| It sounds like a technique I remember calling "controlled carrier". The
| carrier power was reduced when you weren't talking, then was increased
| with the audio in an AGC-like manner. Sounded a little weird, but not
| badly distorted. The objective was to reduce the average dissipation of
| the final stage, so smaller tubes and a lighter duty power supply could
| be used.
|
| But I don't see why you'd use a method like this with a low power
| transmitter, since it's trivial to make one that easily handles the
| power requirements of standard AM. So I don't really think that's what
| is meant by "swing". I'd bet good money that whatever "swing" is, it
| doesn't improve quality or signal strength, and very likely introduces
| distortion that causes splatter. If the transmitter was designed for
| 100% modulation of a 4 watt carrier, and you reduce the carrier without
| a proportional reduction of the audio, you'll be overmodulating and
| consequently distorting and splattering.
|
| What are the supposed benefits of this "swing"?
|
| Roy Lewallen, W7EL

To reduce the drive power to an amplifier and make the modulation louder.

Chris

This should be fine if you're not after a great deal of accuracy.

I think the biggest problem you'll have is insuring that the load really is 50 ohms and resistive, and that your divider is doing what you think. It doesn't take very much inductance at all at HF to produce a reactance that's a good sized fraction of 50 ohms. Also, if you're tapping into a transmission line, it can be extremely difficult to maintain a 50 ohm environment at the measurement point. I don't really know what level of accuracy you can easily achieve, but I do see the possibility for some fairly large errors to creep in without being obvious. I'd recommend trying to calibrate against some known standard if at all possible, to get an idea of what kind of accuracy you're achieving.

I see. But reducing the carrier won't make the modulation louder, only more distorted.

Well, let me back up a little. What I said is true if the modulation is 100%.

But let's suppose that the transmitter is capable of only 50% modulation. In that case, you *can* make the modulation louder by increasing the amount of audio applied to the carrier. If the transmitter is fundamentally designed to handle 100% modulation, this would require only more audio gain or a "hotter" microphone. That would be the best way to make your modulation louder.

But let's say that instead, you reduce the carrier from 4 watts to 1. Then the 1 watt carrier would be 100% modulated. (100% modulation of a 4 watt carrier takes 2 watts. 50% modulation takes only 1/2 watt, which will modulate a 1 watt carrier 100%.) Now you have 100% modulation of the 1 watt carrier. There's the same amount of transmitted audio power as before -- 1/2 watt --, so you're really not making the audio any stronger, and no one will be able to copy you any better than before. (In fact, your weaker signal will have more trouble getting through in the presence of noise or interference.) But if you're the only signal being heard, the receiver's AGC (automatic gain control) will react to your weaker carrier by turning up the receiver's gain, making the audio sound louder. The person receiving your signal can make your audio just as loud with a 4 watt carrier by manually turning up the volume.

So I'll relent and say that reducing the carrier might make your audio sound louder -- but only if your transmitter is undermodulated in the first place, there's no stronger signal to control the receiver AGC, and if you don't reduce the carrier so much that it makes the modulation exceed 100%. But your ability to get through interference and noise will probably be reduced.

In amplitude modulation, the strength - "amplitude" - of the carrier is
adjusted by the audio you wish to transmit.

The degree to which this strength is adjusted is the "modulation
percentage". If the carrier is cut completely at negative voice peaks,
and strengthened to twice its normal level at positive peaks, then the
signal is said to be "100% modulated".

The receiver at the other end can only detect the *changes* in carrier
strength - not the carrier itself. If you reduce the modulation
percentage, you reduce the strength of the changes - the strength of the
signal the other guy can hear.

On the other hand, the laws of physics prohibit negative power. Once
you've modulated 100% - and reduced the carrier to zero at negative
peaks - you CAN'T go any further. It's physically impossible. If you
try, you'll generate sharp cutoffs that result in "splatter" - strong
interfering noises in adjacent channels. (and your signal on the
channel you're meaning to transmit on will become seriously distorted
and difficult to understand) [0]

So the point is, you want to modulate as close to 100% as practical
while ensuring you never *exceed* 100%.

For normal "high-level" modulation the amount of audio power required to
achieve 100% modulation is half the RF power. A 4-watt carrier requires
two watts of audio to modulate it 100%.

http://www.w9wi.com

[0] It is possible to exceed 100% in the *positive* direction -
increasing the carrier beyond twice its normal level - without causing
distortion and interference. Such schemes are common at AM broadcast
stations. I'm not aware of any CB radio that contains such a circuit.

No, "controlled carrier" was something else.

In >100% positive modulation, the carrier amplitude is constant
regardless of program material. You (somehow!) maintain proper absolute
phase through the chain so that you know a positive-going audio signal
at the transmitter audio input terminals will result in increasing power
in the modulated carrier. You then allow the positive-going signal
peaks to exceed 100% while limiting negative-going peaks to less than
100%. Broadcast modulation monitors are able to display negative-going
and positive-going modulation peaks independently.

(at a broadcast station, the FCC requires that carrier power be between
-- IIRC, my copy of Part 73 is missing -- 80 and 110% of the authorized
figure. DX-60B-style controlled carrier wouldn't comply, though I
suppose you could develop a system that didn't swing the carrier quite
as far.)

A quick web search shows that what I described is properly called
"dynamic carrier control". My mistake. I only recall having seen one
such amateur transmitter, and it was over 40 years ago. . .

> they got a higher grade of licence?

I don't think you read my posting properly. I already told you, "every M3 I have met is on his way to the full license. Several have got theirs since I first knew them". Just one example immediately springs to mind without me even having to look up callsigns in my log: Ken M3NPD now M0RZZ.

I can imagine why many people wanting a full license might want to get an intermediate license first, so they could get on air whilst working for the full license. Seems to me to be quite a sensible approach. Others might become M3 because the full license seems daunting. When they get on air perhaps they'd be enthused enough to upgrade their license.

> You would seem to be describing a CBers-Masquerading-As-
> -Radio-Hams and not actually _REAL_ Radio Hams.

This comment shows you're not really thinking logically about all this, even if it is your genuinely held opinion. By your statement you're saying a full license holder can still be a Masquerading CB'er, because he isn't very involved technically. Conversely you would then have to concede that a technically able M3 was a real ham not a CB'er, regardless of his license class. I think you need to decide whether your sweeping generalisations are to define criteria based on license class, or on technical ability.

> I am not mocking anybody - your comment says more
> about you, perhaps, than it does about me?

Belittle would have perhaps been a better word. You are attempting to belittle others more worthy of the amatuer license than you are, and in the process you are demonstrating considerable expertise in self-belittlement...

73

Hans

CB'er Masquerading as Radio Ham, a.k.a. G0UPL (who has never owned or operated a commercial rig, and in gradually making my way higher in frequency from my start on 80m, is still some 17MHz short of the CB band...)

I owned one, a Heath DX-60B. Got my General in 1974, DSB-carrier AM
phone was already essentially obsolete. When I got a 33 signal report
from a 40-meter station four miles away, I decided to stick to CW<grin>...

Seems to me there was a circuit for homebrewing dynamic carrier control
in the ARRL Handbook for awhile.

I think I've got it figured out. For AM, the carrier should be 1/8 of the PEP maximum or 1/4 of the max carrier. So an amp rated 100W AM/FM/CW, 200 WPEP SSB should run with a 25 W carrier on AM. Does that sound right to everyone?

> control the speed of direct current.

Control the SPEED of direct current??? Other than using wire of
different velocity factor or doping the conductor, I cannot think of
many ways you can do this! You can certainly make the motor
speed change (what's new with that idea?? PWM has been around
for half a century or more...), but ya'll ain't gonna do much about
the speed of electrons in a wire to any meaningful degree. And why
would you want to?? Electrons seem to work just fine at the speeds
they achieve in wire - so why not just leave them alone?

Dave

If you want to be thought of as a CBer, then make personal
comments as you do below.

I do not have to, and neither do I, concede what you suggest. The
M3/CB Fools' Licence is judged by the entry standard, which
is no technical standard whatsoever. The few examples that
you _CLAIM_ do not change the essence of the M3/CB Licensee
class which is a Mongolian horde of non-technical turnip-brains,
who are the death of _REAL_ Ham Radio.

I am not making any sweeping generalisations, I am quoting facts.

Indeed, if you wish to be respected as a debating respondent, then
you would do well to avoid the rather silly and childish asides
that you are increasingly using, childish asides that are usually the
mark of a failing debater.

I am neither mocking nor belittling - your comment says more
about you, perhaps, than it does about me?

Once again you are resorting to a rather silly and childish line
in personal remarks, remarks which would tend to classify you as a CBer,
because Ham Radio has traditions of gentlemanly conduct which
are sadly lost on you. Because of your emotive and immature stance
it is unlikely that anyone reading this NG would mistake you
for a Radio Ham.

It is not a question of belittlement nor of mocking, merely one
of taxonomy.

I welcome and encourage everybody, irrespective of their background
to become technically interested and thus become suitable candidates
for _REAL_ Ham Radio. Those that do not become technically
motivated simply are not _REAL_ Radio Hams. They are something
else, probably CBers. Those whose pursuit is football supporting and
nothing else are clearly not Radio Hams, but it not a matter of mocking
nor is a matter of belittling to classify them as non-Hams.

Zero. As universally used, SSB means "single sideband suppressed carrier". There is no transmitted carrier in this mode.

And, modulation percentage has no meaning when talking about SSB, since it refers to the relationship between the modulation and the carrier.

While the conversion from PEP to RMS is simple for a sine wave or other simple waveform, it's not simple when dealing with a real voice waveform. It depends heavily on the characteristics of the voice, and any audio processing (such as compression or RF clipping) that might be taking place. Typically, the PEP value of an unprocessed voice waveform is many times the RMS value.

You're dead right of course Peter.

i believe you're AM broadcasters are limited to 125% positive while here
in the UK we have 100% positive peak limit.

FYI the late model Nautel PDM broadcast transmitters are capable of
around 200% positive peak and up to 50KHz in frequency response!

Broadcast transmitters are limited for obvious reasons.

>73 Gary N4AST

Resistive dividers don't work worth a crap at rf, unless you use
non-inductive resistors, and then you must consider that your input
to the squaring circuit will have some capacitance to ground, who's
ability to screw up your higher frequency readings will be astronomical.
Why the squaring circuit?

Bottom line is this, all the resistive ladders I have played with
were worthless unless they contained capacitive compensation, which
can be found only by trial and error. I prefer a 'T' connection with
a good quality 'coaxial pad' of 10 db, then I feed it to my Tek 2215A
scope. It's deadly accurate from D.C. to at least 30mhz. More accurate
than any of my inline wattmeters, with the exception of the 'BIRD', and
that is only good across the spectrum of the slug I use.

So, like the Russian Woodpecker, just swamp it with about 10 hams
running full legal limit, and keying quickly, and randomly. Maybe
you can chase it away. Or maybe find it's source, and destroy it,
and it's owners. It continues to piss me off that 'official' agencies
think nothing of plopping signals right in the middle of amatuer
bands, and shitting on us, even thought there are rules that forbid
such uses of our frequencies. Gee, wasn't it possible for the signal's
owner to put it over 7.300 mhz. Screw them with a capital F.
I used to love to drive the woodpecker crazy. It was easy to chase it
out of the ham bands. Maybe we can make the 'mystery' signal
useless to it's owners. Now why is it that 'they' could find us
quicker than 'they' can find the mistery signal and eliminate it???
Hahaha, wish I still had access to some 500kw Navy shorebased
rhombic stuff. Although the rhombics probably would not be facing
the correct direction. At one time I may have been able to swamp
their receiver into oblivian.

Just the ramblings of another pissed off ham who hates folks using
hambands 'without our prior consent'.

>anyone have any info on how to do this or a schematic for this radio? Thanks
>
There was a radio mod guy who came around to the east coast fests. He had
a mod that flipped the transmit and receive vco's. Your 7850 would then
receive 10.7 higher than indicated, but with reduced sensetivity. You could
select modified/normal opration by wiring this mod through one of the
'priority' switches on the front panel. I made this mod to my kw TR-2400
HT and it worked well. The vco's for the TR-7850 are not totally unrelated.

Best of luck.

If you would 'google' it up, you would find that the military prempts the FCC and can operate just about anywhere they want without 'permission' from the FCC. I found some military stuff right in the middle of our 450 band a couple years ago, and challenged the operator. He was only to glad to give me a phone number to call, which I did, I ended up at a military base talking to a high ranking officer who directed me to several web sites that explained it all. He was right, they were legal, and I was supposed to 'bug off' whenever I heard them even though my ham license said I could operate there. The FCC couldn't do a thing about it...

Hello everybody:

Does anybody have a copy of the service manuals Vol I and II for a Tek 2754P spectrum analyzer?
Or any place where I could get them?

Any review of the 2754P?? I just got one......it nees a little bit of work.......

Thank you

2524. Re: Wattmeter Location

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-09-16 05:33:50 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <10ki9e21u5kvu6a@corp.supernews.com>
Source record: 23207

The problem with a plain resistive divider is that the detector (or, in the case of a scope probe, the scope input) invariably has an associated shunt C. Without compensation, the lower arm of the divider gets less voltage than it should, due to that shunt C. If the capacitive reactance is high compared to the resistance of the lower divider arm at the highest frequency of interest, then you can probably get by without shunt capacitors. But otherwise, you need to make a compensated attenuator by putting C across at least the upper divider arm.

The rule for making a compensated divider is that the time constants of the top and bottom should be equal. That is, R1C1 = R2C2 where R1 and C1 are the parallel R and C at the bottom of the divider, and R2 and C2 at the top.

This kind of divider has a theoretically flat frequency response, that is, the voltage at the tap is constant assuming that the voltage applied to the top of the divider is constant. But there's the rub. The impedance of the divider is *not* constant with frequency -- because of the C, it decreases as frequency increases. So depending on the circuit it's put across, above some frequency the divider will begin disturbing the circuit being measured due to the divider's too-low impedance. Consequently, the design procedure is usually to first minimize the detector or load C. This allows you to use the smallest possible C in the top part of the divider, resulting in minimized loading of the circuit to be measured. In general, you don't want to add physical C to the lower part of the divider, unless the load (detector) C is variable, unpredictable, or nonlinear, which requires it to be swamped by a known, fixed, good-quality C.

Even such a simple circuit isn't trivial, if very accurate division and wide frequency response (or fast and low-aberration time response) are required. "Hook", "soak", and other nonlinear effects are well-known to designers of oscilloscope front ends, as are the tricks and skills necessary to avoid them. But these problems are much worse for high impedance dividers than ones designed to operate in a low impedance environment like 50 ohms.

For the 420-450 band in particular (and many of the other UHF bands as
well), the FCC's allocation of these bands to the amateur radio
service is "secondary", with government users being the "primary".
Amateurs "must not interfere" with the government users and "must
tolerate" interference from government users. There are certain other
services which have been granted "primary" use of these bands in
certain parts of the country, as well, and amateurs must not interfere
with these.

FWIW, I didn't see any indication in the ARRL article which suggested
that the 7238 kHz carrier cluster is from a government operation, and
as the signal doesn't appear to be actually carrying significant
intelligence in its carrier or sidebands it may just be some odd piece
of equipment which has started oscillating strangely.

I'll be really interested to learn what it eventually turns out to be.

I do humbly apologise, I am clearly in desperate need of a good period of solitary monastic study alone with my Oxford dictionary. I appear to have completely misunderstood the meaning of such words as mocking, belittling or taxonomy.

Any M3'ers listening... please be advised that:

You are all CB Fools
You are a Mongolian horde of non-technical turnip-brains
You are the death of real ham radio
You are comparable to needleworkers and football supporters

Gareth G4SDW, in the best traditions of gentlemanly amateur radio conduct, has spoken. Of course, he is not mocking you, nor belittling you. How could you ever think such a thing? On the contrary, he is welcoming and encouraging you enthusiastic newcomers into the world of amateur radio.

73

Hans G0UPL

Childish failed debater, emotive and immature CB'er masquerading as radio ham.
a.k.a. G0UPL.

About 25 years ago a place was maiking 27 mhz CB amplifiers using them in combinations of 4 to 12 of the 1625 tubes, the 12 volt version of the 807. They would put out about 25 watts of carrier for each tube used. The circuit used was push pull. It seemed to be a copy of a design in a very old QST (maybe a 50's version) design . I don't know how clean the output was but the amplifier sounded fine on the receiving end. I would guess that for ssb you could push the output to 3 or 4 times this ammount.

You're kidding, right?

The 807 was the most-used amplifier tube in history. It still beats the 6146 in popularity, given the time it was used. From audiophile tube amps, to RF modulators to RF linears and class-C self excited power oscillators, the 807 was/is there :-)

RF schematics are all over. Check Google, check the ARRL Handbook, CB websites and pirate radio websites.

Russia and China still make it. Russian ones are the best and called G-807.

If you want to play with an 807 at audio, for all practical purposes, it's a 6L6GC ;-)

Yes, In fact the Navy, and other groups operated American OTH radar
sites on the west coast. However, at the time (mid 70's to mid 80's)
the Russians (USSR) either had a similar OTH radar system, or, at
least realized they could key a high power array at 10hz and boone doggel
the American OTH. Perhaps the Russians had no return echo screens,
and no radar system at all, but they loved sending those annoying
clicks easterly off their eastern shores.

Let's take a parallel here - there are some doctors who are absolute quacks and duffers despite their training. There are several unqualified quacks, reflexologists, aromatherapists, herbalists, folk mediciners, etc, who are actually quite interested in how the human body works.Logically, from the argument that you present below, you would be quite happy for any of these latter unqualified but enthusiastic quacks to operate upon you?

Sounds like an interesting mod. I guess it works by piping a copy of the tx osc output into the PLL output and disabling the built in PLL. I have the schematic and block diagram for this radio now and might give it a shot. Not too worried about senstivety, seems like every gov't transmission puts the meter in the red. Currently I put dip switches in the PLL so i can select what Mhz i want manually (khz is done through the panel), however this only works to 148.490 then at 148.500 for some reason it needs to roll over and go from loading about 2780 to 4096, rather than 2781 , 2782 etc. Not sure why it does that or how it could still work a mere 10khz higher with that dramatic shift, but thats how it was designed and it does work for some reason.

2541. HF amplifier with PNP

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-09-16 16:50:20 UTC
From: PaoloC <ollollo@hotpop.com>
Message-ID: <2qtufgF14ac31U1@uni-berlin.de>
Source record: 23225

Hi,
I feel a little lazy today, and Mr. Google didn't return anything useful
to my searches.

Can anyone point me to a circuit diagram of an HF amplifier that uses a
PNP transistor instead of NPN?

I know that they behave the opposite, but unfortunately I haven't been
designing BJT amplifiers in the past years and I'm now a bit lost.

I have some spare PNP power transistors with a decent GBW (or ft), and
I'd like to see what happens if I use them as the PA stage of my
homebrew CW transmitters.

Thanks,
Paolo IK1ZYW

>
There are MANY variations on the 807. The 807 is actually a 6L6G with
a plate cap. The 6L6GC has a bit more plate rating than the 6L6.
The 6BG6G/6BG6GA sweep tube is an 807 with an octal base, minus some
sheilding.
The 1625 is an 807 with a medium 7 pin base and a 12.6 volt heater.
The 807W is a smaller squat glass version of the 807 that is more
rugged. It can be pushed harder.

Some 1625's and 807's had the beam deflection plates (suppressor)
brought through the glass with their own wire lead connected to
the cathode at the base. You can debase these tubes and connect the
suppressor to it's own pin (1625) or tie it to one of the
grids (807) and then run the tube in true grounded grid operation.
There were quite a few linears in the 50's built this way.

I recall one amp used a voltage quadrupler to get 600 volts from
the 120v ac line and had 10 tubes with the heaters wired in series.
One tube was a driver, and 9 were grounded grid finals.
(A bit of a shock hazzard perhaps.)

SemiConductor Theory

(c) 1997 by Gareth Alun Evans

A transistor is rather like the human alimentary canal, after the
typical USA diet of burgers and chips; - it constipates, as do
semiconductor diodes with no applied bias - the available holes get
filled in and nothing can move.
The base current is like a small application of laxative; some of
the constipation passes through, until the effect of the laxative wears
off. The total throughput depends upon the Mobility. By applying a
continuous feed of laxative, then a continuous current passes through.
Applying too much laxative results in saturation - ie, there is a limit
to the maximum throughput, depending on the external circuit; in this
case, the maximum rate at which you can feed in the burgers at one end.
(If you are a customer of MacDonalds's, here in Chippenham, Wiltshire,
UK then this rate is very low - I have been there twice, and both times,
the service was *APPALLING*.)
The difference between PNP and NPN is the direction. In the old
days, PNP was used, whereby one injected from the rear end, using a sort
of huge syringe - hence PNP - "Put-in Near Poo". More recently NPN is
more common, where the laxative is entered via a carrier of some sort,
usually chocolate and so we have NPN - "Now Pleasant Nutrient".
Despite the adverse effects, the USA diet of burgers and chips
carries on, and recourse has to be made once again to the chocolate. Now
the ratio of the carriers of the constipation, the burgers and chips, is
much higher than that of the chocolate. Thus they are referred to as the

Majority Carriers and the Minority Carriers. If you indulge too much, you find that the vendor will provide you with a paper bag, known as an Excess Carrier.
More recently, there are problems with impurities and you find that the opposite effect occurs. You have no time to reach home before diarrhoea takes over. You have no option but to stop the car and nip over a gate into a field. Hence the Field Effect Transistor. This time you have to inject something to STOP the flow. Now, assuming that there was a certain control over events; nothing happened until the Gate was encountered, you then became the Source of flow, and the field itself acted as the Drain. What was originally dirt, became grass, was consumed by the Cow, you ate it as a burger, and it has now returned to the topsoil, an effect known in the trade as Surface Recombination.
(Incidentally, did you know that Diarrhoea is hereditary? Apparently it runs in the jeans.)
Some of the impurities accumulate in your rear end, and no matter how valiently you try, you cannot rid yourself of them. Hence In-de-Bum is known as a Try-Valient Impurity. In the same way, Arse-nic, well known for its ill-effects and accumulation in the body tissues is known as a Pent-Up-Valient Impurity.

The thing that immediately pops to mind about an old 807-based
push-pull parallel amp (6 tubes) was that it was a #$!!*% to
neutralize!

Cross over neutralization circuit should be simple
to set up. A six tube 807 circuit should have about
the same g-p cap as say a 2 tube 811A setup, though
a bit more output C (would be absorbed into the tank
though). Trick with 807's is to sub mount the tubes
below the chassis so the bottom of the plate
is just a hair above the chassis. This lets the chassis
serve as a shield between the plate and the grid circuits.
Millen sold a tube shield for the 807 that would do the
same thing with the socket mounted at chassis level.

2546. Miami area Ham or Radio Tech/Engineer?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-09-16 19:25:02 UTC
From: NCSRadio <careyfisher@ncsradio.com>
Message-ID: <OLI2d.166332$%n4.145609@bignews6.bellsouth.net>
Source record: 23230
Cross-posted to: rec.radio.amateur.homebrew,sci.electronics.design

We're looking for a ham or experienced radio technician/engineer in the Miami area to help a customer of ours to install some audio switching equipment in his company's radio operation. He does HF aircraft communication. He lost his technician and needs to hire someone to get our equipment installed and working.

Anybody in the Miami area with good technical skills need a short term job?

Email me and we'll go from there.

Thanks,

Carey Fisher

Connect it exactly the same as you would an NPN, but reverse the polarity of the power supply voltage. If there's a bias circuit using a diode, the diode (and bias supply polarity, if it's a separate supply) should also be reversed.

If it's necessary for you to use the PNP with a positive supply voltage, it's still possible, but it complicates the circuit, and adequate bypassing becomes essential and sometimes difficult. In that case, a diagram (and preferably a layout) of a known working circuit is desirable.

All other things being equal, a PNP generally has lower ft and higher capacitance than an NPN, which is probably why they're less commonly used. This difference is due to the basic physics of the device (lower mobility of the carriers, as I recall).

The Woodpecker changed frequency all the time anyway, whether anyone tried to interfere with it or not. It was part of their operational plan. And the pulses carried a PSK coded pattern to make it easier to recover the returned echoes, sorting them out of the interference. I doubt very much that anyone could really interfere with them when they operated.

My experience locally was on two meters, but the high-ranking officer
said that if/when it happened again, I should call him and ask to have
their frequency(ies) changed to something that didn't interfere with
whatever we were using.

The Heath DX-60 used "controlled carrier" modulation. It was a
form of screen modulation.

The peak power on AM is 4 times the carrier power. But, don't forget, AM
has TWO sidebands, not one.

I can't find it right now, but somewhere I have an article from a ham
magazine that used TEN of them (actually 1625's), with their filaments
series'd across the 120-volt mains and their outputs paralleled on one
of the lower ham bands.

I, too, have been saving them and will find the round tuit someday.

I always wondered why Motorola (of all peopled) used PNP RF
transistors in the final and two driver stages in their Micor base
station and mobile radios.

Were those perhaps germanium transistors? The first Ge transistors were PNP, and the first (Ge) audio power transistors I recall seeing in wide use, in auto radios, were PNP. I'm not sure why PNP was favored in the early days, whether due to some basic physics reason or some more practical processing or production considerations.

I kind of chuckled at the thought of a handful of gnat-like hams chasing out the 800 pound gorilla Woodpecker. It's reminiscent of the guy doing the little dance. When asked why, he said, "to chase away the lions". "But," came the response, "there aren't any lions within thousands of miles." "See, it works, doesn't it?" said the dancing man.

As Martin points out, the Woodpecker would sit at one frequency for a while, then jump to another -- I heard it many times. But I hadn't realized there were people out there congratulating themselves for chasing it off when it did make one of its frequency jumps.

I am looking for a way to modify an RM KL-40 to accept higher input. Please look at http://www.rmitaly.com/rm/download/manuals/KL40-manual_rel_400.pdf for the schematic. I can put a voltage divider where R2 and R3 are but I have one concern. This would put a resistor in parallel (to DC) with R1, which is between the gate of the MOSFET and ground. Will this affect the circuit?

Thanks,
Chris

Hello Roy

These fairly modern devices, with 211-xx style flange mounts. Although
they were marked with Motorola Communications inhouse numbers,
they appear to have been part of the general Motorola RF transistor
family, with complimentary NPN equivalents.

By "swing", do you mean a slight upwards kick on the power meter
when you're modulating the radio? IFIC, many CB'ers strove for
upward modulation.

the more important limiting parameter for application as ssb linear
amplifier is max cathode current.

It could be mentioned that 4-65 has the same max PEP input as 4-125
because the cathodes are the same

> couple years ago, and challenged the operator.

In general, the military everywhere like to rely on Article 38 of the ITU Conventions.

The first para of Article 38 pretty much says the military radio installations of any country can do whatever they want.

But the second para says "Nevertheless these installations must so far as possible observe statutory provisions relative to ... the measures to be taken to prevent harmful interference [to other services] ..."

Many military people are like other people I know (present company excepted of course HI) - as soon as they find something they like, they stop reading, so they never get to the second paragraph of Article 38.

It may be worth reminding them occasionally that ITU Article 38 is not a blank cheque.

Remember, each time the wire passes through the core is counted as a turn. In other words, just passing the wire straight through the core is one turn. 24 gauge wire should be fairly easy to get 40 turns in a single pass. Toroids are usually wound about 330 degrees around (a 30 degree gap between start and end of winding)...

Hi Scott I have tried and no way can i get 40 turns in without
overlapping, also is it correct to wind on only 80 percent of the core

Scott wrote:

Bad Instructions! You can't get 40 turns of 24 on a T50 core in a single layer. Go to #26 or even 28. It won't change the inductance appreciably for the same number of turns, and you can space it properly. Given just the number of turns, you probably won't be within 10 percent of the desired inductance anyway.

No, I am not kidding - if I wanted to use them at audio thats simple enough - havent been able to find many references to them via Google - perhaps you could post a few? - and most designs of the 50's in push pull had bugger all output filtering so were not up to todays more rigorous standards for spectral purity. As well, were reltively low powered. My dilemma is with simple aerials I can hear stations 5 by 9 but they cant here me on a band where everyone is running 400w plus with gain directional antennas. Sure, could buy a Yaesu FL2100, but the price of tubes is outrageous (by my standards, anyway) and the amps using 4CX series are even more so. The Ameritron stuff using 811's look better, but dont have any of them in the junk box - this IS a homebrew website, after all.

Have built in the past with 807's, from fading memeory 2 tubes in push pull would give about 60 watts - since most modern HF rigs give 100 watts, there is little point in doing a design like that except for nostalgia.

I should clarify my question - they are available dirt cheap, (sometimes free) power supply requirements are relatively modest (at 750v plate) and they are certainly more rugged and forgiving than modern ceramic tubes.

And I know the evolution of the things, thats basic radio history.

If you have to overlap turns, overlap adjacent ones, rather than go with two layers. this lowers the additional inter winding capacitance. In effect, you get a single layer on the outside of the core and a double layer on the inside. Have you used the trick of making a bobbin out of a plastic straw or wood splint and notched the ends so wire can be wrapped over the ends? It makes it very much easier to pass a length of wire through the hole, lots of times, without dragging the whole length through for each turn.

You can also tack each turn down on the outside corners of the core with a little drop of instant glue, but you have to be really careful to not glue your fingers to the inductor.

Help, my beloved 20 year old Weller EC2002A Soldering Station has cr@pped out! Although it seems to heat up normally and can even be adjusted, the display only flashes "Err" briefly when turned on. I checked the thermistor in the iron and it seems to be OK. I even bought a used newer but junky looking EC2002-0 controller, but it seems to have other problems and has different parts inside so a swap is not in order.

How does one fix these?
TIA

>
>Roy Lewallen, W7EL

And any of these times that you listened, had you ever heard anyone
intentionally messing with it?? Yes, it would sit a while then move
to some other frequency. But it would sit much shorter if you screwed
with it. Geez, there were even articles written on exactly the keying
rate to chase it away. A kw and a beam on 40, and a keying rate of
just about 10hz would chase it out almost instantly, and if it came
back in short order, a second chase usually drove it off for the rest
of the evening.

Ken,

>I recall one amp used a voltage quadrupler to get 600 volts from
>the 120v ac line and had 10 tubes with the heaters wired in series.
>One tube was a driver, and 9 were grounded grid finals.
>(A bit of a shock hazzard perhaps.)

I've seen something similar here in the UK 20+ years back and remember the amateur who built the thing. I think he was playing around the Kw level and with no transformers in sight.

We do have a head start on you fellas with 240v @ 50Hz :-)

A 'bit' of a shock hazard is kind of an understatement don't you think.

From: Roy Lewallen <w7el@eznec.com>
Message-ID: <10kler08med4fc0@corp.supernews.com>
Source record: 23161

I remember seeing something like that around the '60s, in QST I believe. It was built into a suitcase by a guy who traveled a lot, to be used in hotel rooms. (Imagine the RFI problems!) I don't think that particular one was using 807s, though -- I believe it had some later type of sweep tube that wasn't as tall.

The 807 was, incidentally, used as a sweep tube. In the middle '60s I worked on heavy ground radar (mostly '50s vintage), and the 12 inch PPI (round) radar scopes used push-pull 807s for the deflection. I once had a huge box full of 'em too, but they had to go when we moved from Alaska to the lower 48. They're probably still up there somewhere. . .

Is that from experience? But seriously, I normally tack thing down with a
bit of hot glue and it does come off easily so mistakes aren't much of a
concern.

Joe -

Likely the problem is with the sensor/SCR circuitry on the control board within the EC2002A base unit. 3 choices for repair:

1. You perform component level repair/troubleshooting on control board. Since it has worked for 20 years, it sounds like one of the ICs (display) may have failed. Weller tech support/repair (North Carolina) may be able to help with part numbers.

2. Send unit to Weller for repair

3. Swap out (change out) the EC2002A control board.

Bob Wurth (eBay ID: bjwurth6969) has been selling NOS Weller control boards for the EC series from time to time at reasonable prices (he had a Weller EC1002 control board with no bidders last week).

Joe,

Try to check the electrolytic capacitors. I has one Weller the three capacitors gone. I change them and run again. Check for high ESR on electrolytic capacitors.

Good luck

Eric

CBers are very susceptible to urban myth and legend. Not understanding the "normal" nature of an AM carrier, often they won't see the needle move very much (assuming some cowboy jockey hasn't been in the rig snippin' and clippin'), they get kind of excited. "HEY! I ain't got no "swang", so therefore, they think they
aren't "gittin'" out. Voodoo techs have been able to take advantage of this by monkeying around with the sets and/or using funky, cheap meters to show the unknowing how much their radio is "swangin'". "LOOK! Ya got 8
watts o' carrier and 40 watts of 'swang'"! The CB guys eat it up! AND willingly part with $$$ to get this "Swang". Swing is fully embedded in CB psyche and, like the "coax length" (18 FEET! 18 FEET! Ya gots to have 18 feet of coax!!!!!!) bullsh--, it is part of the "holy" grail of CB radio! LMAO!

J

I used to use instant glue a lot, fogging it with my breath, to harden
it very quickly. But I inhaled too much of the fumes and damaged my
lungs, so hardly ever use it, any more. THe hot melt glue idea sounds
interesting. Especially with the ability to peel the whole mess off
when the coil is done.

Jerry, you can trust me when I say that hams have their full share of beliefs in voodoo physics and misunderstandings about how even the simplest phenomena take place. A quick scan of the rec.radio.amateur.antenna archives provides ample evidence in itself, but there's plenty of other evidence scattered about.

So let's not be too hasty at calling the kettle black.

From: Roger and Ute Brown <rogerbrown@gci.net>
Message-ID: <10kmh91lpb17v4c@corp.supernews.com>
Source record: 23171

I have an 833A tube which I will use for a special project. I notice, however, that it seems to have very small flakes deposited inside the envelope. From what I surmise, they apparently jarred loose from the "getter." Has anyone run across this phenomena before - and more importantly, could I expect the tube to function OK with these deposits?

Correction, if you believe the temperature sensor/control SCR portion is
working correctly - a external tmeperature sensor is useful - as you rotate
the temperature knob -- then definitley look for display related (component)
issues - such as mentioned by Eric

2590. FS Ad - TIL311 & DIS1417 Hexadecimal Displays

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-09-18 00:04:29 UTC
From: jr_part@yahoo.com
Message-ID: <b4cd29d.0409171604.7f6f25a1@posting.google.com>
Source record: 23174
Cross-posted to: rec.radio.swap,rec.ham-radio.swap,rec.radio.amateur.homebrew,uk.radio.amateur

- 44 pieces of TIL311 @ $6.00 each (US Funds)

The lot price for all 44 pieces is US$215 or about $4.89 each

The TI TIL-311 is a Hexadecimal Dot Matrix Display with integral
TTL driver electronics to accept, store & display 4-bit binary data,
Epoxy package (Note: This part wholesales at about $16.50 each)

- 4 pieces of DIS1417 @ $7.00 each (US Funds)

The TI DIS-1417 is a House Number version of the TIL311 with extended
temperature range we are told. Otherwise the specs. are the same.

For a copy of the TIL311 Datasheet see:
http://www-s.ti.com/sc/ds/til311.pdf

For pictures of this lot visit:
http://www.geocities.com/jr_part/til311.htm
or http://www.geocities.com/pc_diagnostics/til311.htm

No shipping is included in the above prices. I would
require your full ZIP code or postal code to quote a
total including shipping. Please specify the country for
international orders outside of North America. The shipping
you will be quoted is the cost of the postage stamp (plus
insurance if requested). Displays are new and are the
latest revision.

I wouldn't fret too much about it. Just reduce the wire size to the point where you can easily get it all on one layer (as others have suggested), and it'll be fine.

The fact is that the cores themselves vary quite a bit from one to another, and normal variations in winding technique increase the variability, so any good design either doesn't need for the finished inductor to be a precise value (that is, it's in a relatively low Q circuit), or it has some means (such as a variable capacitor) of adjusting to compensate for variations. In short, it shouldn't really be that critical.

<< I can put a voltage divider where R2 and R3 are but I
have one concern. This would put a resistor in parallel (to DC) with R1,
which is between the gate of the MOSFET and ground. Will this affect the
circuit? >>

Chris-

Yes, it would appear to upset the bias on the MSFT1 gate. R4 is in series with R2//R3 and R1. Current flowing through R1 develops a DC bias voltage on the gate. You should be able to DC-isolate a new shunt resistor by wiring a capacitor in series with it.

Try and keep added components away from the output side of the circuit, or it could turn into an oscillator!

All very good advice:

1. "Check for bad caps on display", yup after 30 years that could be a
problem
2. "Send back to Weller to have them fix." Why didn't I think of that,
probably a lot cheaper than a new one and I like this one!

Thanks Guys!

This must be a major embarrassment for the security services in
Britain. The sheer size of this thing, I mean. And the fact that it
appears to have been designed about 60 years ago and runs off dozens
of penlight cells. Hardly state-of-the-art!
BTW, for anyone that hasn't seen pictures of Gerry Adams looking very
cross standing next to this heap of junk; it's about 6 feet long by
4"X8" and not exactly easily hidden (which is probably why it was
discovered :-))

"Party chairman Mitchel McLaughlin said it was a highly sophisticated device with a large battery pack and the party had no idea how long it had been in place."

He and you apparently have no idea when it was installed so you have no idea what the state of the art was when it was made.

Hey David,
I was trying to find my catalog from Amidon Associates (where I get my toroids) before I opened my mouth and inserted foot and replied to your quandry. In the brochure, they have a listing that tells how many turns for each gauge wire on any given toroid size can be wound in a single layer. Usually, I pick the largest wire that should fit based on the number of turns I need. Right or wrong, that's how I do it. I couldn't find it and I didn't see it on their website either. Anyhow, I assume you are winding with enameled wire? Regarless, good luck with the project and let us all know how it works out!

I would like to build a broad band frequency jammer for the FM
broadcast band. I have neighbors that like to play that damn music too
loud all day long. I figure if they turn it load and their station
goes off the air for a while they might get the message. ;-) :-D
If they keep the volume at a respectful level they will be allowed to
listen to their music as they wish as long as I don't have to listen
to it at uncomfortable levels.
I know this is entirely illegal and don't care about it. This is war
(!!!)and I plan on winning.
If you have plans for something that would help me achieve my goal I
would like to hear of it. My electronics skills are advanced (I've
used to build and design "bugs" for many years, I own a good equipped
lab, enough that I could build a project.
I have some experience with rf broadcast circuits.
The proximity of the offending radio's location to my house is quite
near so I don't believe a transmitter with an overly large
power...something between 3-5W
will be enough...LOL....
I'm "jamming" this neighbour with a 5W transmitter, but have to change
the frequency MANUALLY as soon as he changes the station, so I cannot
figure out how to do it automatically...
I'll be VERY THANKFUL for your help and ideas :)
TIA
Nina

No, but probably "Property of HMG" which is near enough the same
thing. :-)

>You don't know
>who made or installed it.

A one-eyed apprentice carpenter, by the look of it. Get those big,
wobbly numbers in marker pen: 1,2,3,4,5,6 so they'd remember which
order the blocks were supposed to be connected up. :-)

>"Party chairman Mitchel McLaughlin said it was a highly sophisticated

Yeah, well he's Irish, isn't he, and probably thinks the electric
light bulb is "highly sophisticated." ;->

>He and you apparently have no idea when it was installed so you have no
>idea what the state of the art was when it was made.

The date stamp on the batteries ought to provide some clue. "Best
before January 1946" would be my guess. :-)

Sounds like you don't need any help, then.
Use one of your old FM bugs and adapt to sweep the band with a
sawtooth generator varying the reverse bias on a suitably chosen
varactor diode as part of the frequency determining section. Then
hitch the output of your bug to a couple of additional broad(ish) band
RF amplification stages which you will no doubt have no problem
designing. Presumably you know all this, anyway.

>The proximity of the offending radio's location to my house is quite

So you want to wipe out the whole of the band to save you the bother
of retuning? I don't think you've thought this through very well. What
about everyone else in the neighbourhood who presumably don't annoy
others with too much volume? They're going to get wiped out, too. 3-5W
can cause quite a bit of widespread local disruption unless you're in
a strong signal area.

You really haven't thought this through have you.
Your neighbor isn't doing anything illegal.
Your plan IS illegal.
You can EASILY be located by the authorities.
STIFF fines are involved.
If you're in the US, all they gotta do is call the FCC
and you're toast.
If you're gonna wage war, you should have a winning strategy.
Your current one ain't!

Nobody has asked you, so I put in the question here.

Are you sure that you have the right toroid?
Maybe you have mixed them up, Maybe the kit is delivered with wrong toroid?

When Vectronic and the kit manual says that it could be done, maybe you are
lookoing in the wrong direction?

Perhaps you'd like to question why 'Terrorist' Gerry Adams didn't spot such
a big thing being installed in the first place and only now chooses to have
his picture taken next door to it whilst looking annoyed.

Perhaps you'd also like to question your own inability to recognise that you
are in fact a sad wanker.

Unfortunately both you and Gerry Adams, and I'm sure he'll be dismayed to be
mentioned in the same sentence as your good self, suffer from the same lack
of competance when it comes to self analysis.

Gerry Adams does it by choice and still believes, you do it because you
can't 'think' any better.

You're both still wankers.

Looks like they originally intended it to be disguised as a desk- but
then the thing consumed so much power, it would lose credibility because
it was getting so warm.

2610. Addendum to "Schematics for building a broad band frequency jammer"

I see no reason to try and jam the entire band. Just put together a simple FM transmitter and as someone earlier suggested, transmit a squeal or something equally irritating over whatever station they're listening to. As M->P suggested, that will be far easier to accomplish technically. If you need schematics for a simple FM transmitter that's very easy to build, yet very effective I can help you there. I've built and used several on this design. In fact, there's a drag strip in GA using a transmitter I built off of this schematic using it to transmit race stats so people can listen in their cars and with head sets so they can hear over the loud car exhaust. Also got the board foil design and component layout making it super simple to build if you want to go the professional route.

> I'm ready to pay for your help if needed.

You will only get yourself in more trouble by jamming their radio.
They can come over and beat you up if/when they find out who is jamming.
You can go to jail or pay heavy fines when the authorities discover you,
and they often need only a few seconds to pinpoint the source of an
offending radio transmission.

A much better alternative is to increase the sound isolation between you
and the neighbor.

Use some wooden planks to build a frame which covers the wall(s) to keep
the construction steady. Put sound isolating material in the frame, use
heave cloth type of materials, like heavy old type mattrasses (not foam
plastic), different types of mats, wool blankets, etc.

Fiber board is also good, combined with thick layers of heavy textiles on
both sides.
Put heavy mats on your floor if the sound comes from there.
Build an inner ceiling if the sound comes from up above.

After soundproofing your apartment, or parts of it, you can use your own
sound source to create a low volume but masking effect which means you
hear a lot less from your neighbors because you have your own favorite
music running day and night.

Another alternative is to talk to them and tell them to stop disturbing
you. That will work if they are actually trying to make you do that.
There are lots of religious people who are actively trying to make their
neighbors strong minded so they can come to God or something like that.

A problem with that approach is that they will probably only be
encouraged by that and start other manipulations to force you to become
even stronger. So you will end up with your brain filled up by the holy
wrath, or the holy spirit, just like their brains.

I can't speak for others, but no amount of money would convince me
to sell out my own ethics so easily.

I suggest you involve your local police. There are likely noise
ordinances in your area which your noisy neighbor may be in violation
of.

OK guys,
Thanx meantime for your responses.
Not getting much help...:(
I know it's illegal, I know it's dangerous, and I know that I can build a huge wall between our houses....
But, I'm still interested to build this device, for reasons that I cannot mention here...
If anyone wants to help me, please do, but I don't like conferences about my skills, or legal advices etc.
TIA to anyone who actually tries to help :)

it appears that most of the proposers have little experience in this
field, the simplest 'jammer' would indeed have much more effect,

use slow morse cw transmitter

it appears that most of the proposers have little experience in this
field, the simplest 'jammer' would indeed have much more effect,

use slow morse cw transmitter - preferably on a legal frequency, 6m
operation is often bad for interference

This site contains some useful info:

http://www.electrokits.com/id-fm_jammer.htm

And try alt.pirate.radio instead of alt.radio.pirate (you won't get
much help from anyone on the mainstream groups for an illegal aim like
you've publicised here, I'm afraid).

>AM 100% modulation is max before distortion of Audio.
> The carrier has 50% of the power, the two sidebands have the other 50%.

Actually the carrier has 2 thirds of the power, and the sidebands 1
third.
A 4 watt carrier "carries" 2 watts of audio when modulated to 100%. Each
sideband is 6dB down (x1/4) on the carrier power (which just sits there,
remaining constant). The peak envelope power is 4 times the carrier
power (ie 16 watts), but there's only 2 watts of 'speech' there. This is
why SSB is more effective.

>

>4 watt is 4 watt, why turn it down, urban rumor

I'm wondering if anybody out there has successfully replaced the analog processor portion of this circuit with a micro?? Would like to hear from you as I'm contemplating the same.

First time around it was to jam a neighbor's loud radio, this time
around you can't say what it _really_ is.

First time around you knew it was illegal, this time around you still
know it, but you don't want to hear about it _and_ you want someone to
help you even though you've said you know it's illegal?

You're not the sharpest knife in the drawer, huh, Nina?

Source record: 23064
Cross-posted to: rec.radio.swap,rec.radio.amateur.homebrew,rec.radio.amateur.equipment

I have a TS450 that is coming back from the repair shop as costing more than it is worth to have it fixed. I suffered some sort of indirect lightning pulse, as it did not have an antenna connected and was turned off. The guy said that the IF board was bad, for sure, and maybe more. Therefore I am going to try and fix it in my spare time, which means it may sit for a long time. I would not bother, but the radio looks like a mint piece of equipment. So if someone has one that looks like crap, and has some good boards (especially the IF board), I would like to talk. Also would consider buying boards...

2631. MS1307 and IRF520 rumors

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-09-19 00:33:10 UTC
From: Chris <REMOVEchris1379ME@bigfoot.com>
Message-ID: <at43d.1338$qA6.1022@newsread3.news.pas.earthlink.net>
Source record: 23066

Maybe somebody here can answer my question. The MS1307 is a MOSFET used in several HF amplifiers. All the ones I've seen have the numbers filed off. It is rumoured that these are just IRF520's with the numbers removed. Has anyone else heard this?

Chris

Hehehe. The little unit I was describing is good for about a mile radius with a properly tuned vertical dipole. I've used one in a convoy so everyone in the group could listen to the same jams on the trip.

This page thinks so:

http://www.xs4all.nl/~barendh/Cateng/Cateng_fet.htm

25W HF power is not out of the question for an IRF520 @14V.
I used to get 40W on 20m out of IRF510s, the IRF520 probably
has less gain than the IRF510 but more power-handling ability.

Looking for info on building a bandscope/spectrum display to adapt to
a Kenwood TS-2000. Google turned up a few ideas but nothing usefull.
Planning to interface the receiver broadband IF prior to DSP filtering
to an adapter of some sort then into a PC for processing and display
of at least a 100 khz band spectrum. Anyone know of such a device and
where I might find technical information to build one. 73.s and TIA

9 vdc keeps it legal, but it'll take considerably more.
As far as the final... ugh... IIRC the final was a 2N3096, but I'm not
sure now. It's been quite a few years since I did anything with that
print. Will post when I've got it up.

Don't recall now. Was thinking the 2N3906 would handle 1.5 W, but my books are at the office... and that may not have been the final anyway. I just don't remember. I do recall that heat dissipation, not max VCEO was the limiting factor on the power output and hence input voltage. Will post when I have it.

The nice thing about this little gadget is that it can be built on a board the same size as the 9v battery driving it making for a very compact unit and it'll still make a mile with a decent antenna. Actually, I've got plans for much smaller transmitters designed for use as "bugs" that aren't much larger than the 2032 button cells that drive them although the range is considerably less. I've never bothered to assemble one though. This sort of thing would be just an experimental toy to me as I have no real use for such.

I have seen gettter material 'fall off' the glass before. I would
say be careful not to get any of it lodged into the grid structure,
and all I can say is 'light it up' and throw on some plate current.
As long as the getter is not white in color which indicates a cracked
envelope, and as long as it doesn't glow blue like a mercury vapor
rectifier, you should be A-O.K. I have run these tubes with what
looked like the whole center of the getter flash missing. No problems!

Ya, exactly the same thing I did for the drag strip. This wasn't a kit
though. I don't recall who did the circuit design or where I got it
from but it was just a schematic and description. I did the board foil
design for it on a computer several years ago and built a few.

2642. Spec for NDK TXCO

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-09-19 10:41:01 UTC
From: mike@corn2.freeserve.co.uk
Message-ID: <414d5f0e.146923818@news.freeserve.net>
Source record: 23076

I've just ripped a surface mount 12.8Mhz TCXO from a Sanyo CMP351E
phone.
Its manufactured by NDK, measures about 10mm by 8mm by 4mm, has four
connections and has the markings...

NDK
JPN.
4911
12.8
5111A-ANL50

Ok, I know its a 12.8Mhz oscillator and as it only has four
connections and a trimmer its likly to be a simple TCXO or maybe a
Voltage and TCXO. what I don't know is the pin-out and operating
voltage.

NDK's website has nothing like it that I can find and Google comes up
nada.
Can anyone help with either some solid info or a safe means of
"playing with it" without killing it.

Thanks, Mike W, G8NXD qthr

Nina,

I'm not being funny here, but have you tried asking them politely to turn their music down? I used to have a similar problem with my neighbours, and I found polite requests surprisingly effective. It may be worth talking to other neighbours to see if they are also annoyed by the load music as, obviously, the more people on your side the more likely the noisy neighbours are to realise that they are in the wrong.

Another thing I would recommend is that you look up the appropriate local laws. For example, here it in England it is an offence to cause a "statutory noise nuisance", which is defined as any noise which causes "unreasonable disturbance to the use and enjoyment of one's property". Persistent offenders can be fined up to 5000 UKP (about $9000).

As others have said, deliberately jamming their radio could get you into serious trouble, maybe even a few months in jail.

Gareth.

Personally, I don't place any stock in someone being able to chase away
the woodpecker. In the early 80s I operated from Reifenberg Germany as
DA2EU. I mostly worked 15 Meters CW. When the woodpecker came on line it

was like someone stuck a hot poker through your head phones. You felt like a cartoon character, with the headphones bouncing away from your head. The signal was so strong it completely swamped the receiver and it was being swept over the entire band. They may have been sweeping further, but that's all I was able to determine.

But each time it only lasted 3 or 4 minutes. When it went away the whole band was quiet, and then slowly came back to life. I doubt that anyone was able to do much to stop or deter it.

PNP transistors were more common in the days when germanium was
the semicoductor material of choice, with silicon NPN is the more
common type. The material used just happens to 'work better' with
one polarity than the other. Even so, there are some good HF pnp
power transistors, but as you go higher in power and frequency
they become rarer and more expensive. For QRP hf the 2N2905/7
is a good PNP output transistor (1-5w), and you can use
2-4 in pp/p.

If sending via USPS, UPS, FedEx -- you have to make sure that there are no stickers or barcodes on the package --

Don't forget that kicking and screaming sometimes work with FedEx -- but if you paid the "saver" rate option, they will delay the package until the last moment.

FWIW -- I almost always specify USPost Office "Prioirty Mail" -- If I get my Digikey orders in during the early afternoon they arrive from Minnesota the next day, and Saturday's aren't a problem.

And on the other hand, I ordered a computer
case and power supply at about 3 P.M. last
Wednesday. It arrived about the same hour
on Friday. It's over 700 miles between City
of Industry (L.A.) and Alturas, CA. FedEx
Express Saver service has been good to me.

BTW, there were a lot of barcodes on the
box other than FedEx's. Didn't seem to
matter.

Bill -

Unfortunately, it really depends which provider/logistics company (e.g., UPS, USPS, FedEx, DHL) service is best where you wish to ship - from point A to point B.

I have been disappointed with all carriers, but the FedEx Ground (Home Delivery) service in the Chicago area is probably the worst - they missed more Christmas deliveries and could not tell you where the package was - poor tracking system (different than regular FedEx) -- and shaky customer service .

I just sent a huge box (24x24x30 or so, about 70 pounds) via FedEx 3-day Express Saver from Seattle to Portland. It got there the next day for about $80. Can't complain about that! Actually paying for overnight deliver would have been in the $300 range.

I don't have much use for FedEx Ground, though. FedEx has done a terrible job integrating the ground service with the rest of their tracking and billing infrastructure. The impression I get is that FedEx's IT people are among the least competent in the shipping business. It's *very* rare that all of the features at fedex.com actually work at any given moment. And I've lost track of the number of "user IDs" I've had to create over the past few years due to their wholesale re-engineering of the site.

Perhaps the package is in the building or truck but can't be seen ?

Been using fedex ground for last year now, less expensive the ups
and packages get there on time, I'm in central nc so fedex hub right
here is town.
Kinkos now part of fed ex, so same great rates and more places
to drop it off.
I find the fedex hub faster and easier to use, they know their stuff.

agree with other poster that the fedex ground fedex home tracking is
slow to update. Had one buyer complain about his package,
turns out it was sitting on the front porch since 4 pm california time
but he kept using the fedex home tracking and 'on truck for delivery'
kept showing up ! lol.

Well...
Thanx all who tried to help me in any way :)
The whole "story" is:
The main problem is the guy I'm dealing with...He is a mentally ill
guy, that has been freed from a madhouse about 3 month ago. He lives
in his 14 room yard (yes, he sleeps there too) and has conflicts with
all authorities, including police. He's arrested from time to time for
violence against his wife or children or neighbours, but released
after a few hours, as he is - as I said - insane, and the authorities
are powerless against him. He is really ill, but not stupid. He lowers
the volume between 14:00-16:00 and from 00:00 up to 06:00. Lower, not
closing...
Our windows are about 10m from his yeard, so you can imagine...
I've considered all the suggestions some of the members gave, as
others have said, jamming his radio could get me into serious
troubles, and changed my "jammer" with a 50-100mW module...It has
about the same effect.

So, it is very simple. Figure out what station he's listening to,
setup a transmitter on that same frequency (this isn't hard), adjust
the power, so it goes for at least 100M, and broadcast intermittent
messages.

Tell him things like, "you need to go to sleeeeep...." Or maybe,
"they're coming! quick, shutoff the radio!"

Not to recommend that you break FCC rules, but you probably would get minimum hassle using VCO. Note that 3-5W might get a few people you don't want to get. :)

Get high-speed VCO that can cover your range, then drive the input with another oscillator that causes the VCO to step sweep over FM band. Or, instead, you can drive VCO with D/A whose input is PRNG.

But if you really want to get clever, get digital FM receiver chipset, VCO, etc, and make a circuit that allows you to force your neighbor to listen to the station you want him to listen to, by taking the output from the tuner and regenerating it in a spread-spectrum fashion, pausing at each allocated band just long enough to make your station detectable. Of you use mic or line-out of computer with "disturbing sounds on hard disk" to be replayed....

Or you could just knock on door and use oldest analog device known to man - the mouth.

Thanx for the ideas, I'll try that right away :)

The second part, the analog "device" .... I've tried it several times
before, you can believe me that it's easier for me to ask him...if
only he has been a normal person...but he is - as mentioned before -
insane, mad. He never even answered to my request, and believe me,
I've been as polite as I could. Never tried to argue with him, or
trying to offend him. Just asked him to lower the receiver's volume so
we can rest for a while.
Now I have to close all my windows and use air condition 24/24...

Wow people !!!
I'm feeling now as a killer !!! I'm breaking the laws !!! I'm not a
honest person !!! I'll go to HELL !!!
The police is near to my door with sophisticated devices - just to
catch a criminal...Ben Laden is a kid for me... what else ??????????
I've just asked for a simple idea or schematic - and I've been so
blamed I'm afraid to look in the mirror...
When I asked your help I did it AFTER trying all other options you
wrote, AFTER being polite, AFTER the involvement of the law...
Maybe my reqest sounds stupid or maybe I AM STUPID, but I'd like to
see any of you my friends in my situation, without resting time even
in holidays, withot any help. After suffering all day long without a
posibility to open a window in the house...I'm almost sure that if
anyone of you would be bothered day and night by a lunatic, without

any chance to get help from anyone, even from legal authorities -
you'll loose the "polite" word from your lexicon...
What I know is I won't sale my house, and I'll fight back.
Even it's not legal...

Sometimes what we ask for isn't what we really want.

Your real objective is not to build a transmitter, but rather, to stop
the noise, am I right?

Seems to me that if you were given two options, one of which could lead
to a hefty fine and possible prison time, and another that wouldn't,
you'd surely prefer the safe option. But maybe not.

If you do succeed in building a suitable device, you must be sure he never able to establish that you're behind it. These kind of people often experience persecution mania at the best of times. You don't want to be an obvious identifiable target for all those years of suffering he believes he experienced through being persecuted by others and have him believe that you're in league with the 'dark forces' that have made his life a misery.

FedEx Ground can be disappointing -- I agree -- but I've sold a lot of bulky stuff on EBay and warn the purchaser that they should expect delivery in "at best" a week. Nothing has gotten lost for me via FedEx Ground.

I've come to prefer FedEx Ground over the corresponding UPS service
for one significant reason: damage. Both in my own experience, and
that of the shipping/receiving guy at the company I work for, the odds
of a decently-packaged device being damaged in shipment are
significantly higher if it's sent by UPS.

FedEx seems to be somewhat more gentle with the packages, and (if I'm
shipping and do so via my employer's system) it's less expensive.

Here some options I would recommend:
1: Find an old grandpa with a HAM radio setup and old high power HF amplifier. Pull a wire across your yard (dipole) and hook it up to the antenna tuner and the amp. Then let the old man ragchew with his buddies on the air while he is overdriving the hell out the amp. This will produce very high rf and interference, will get picked up in this stereo speaker wires and will make the loudest noize possible. The best part this is LEGAL and it will jam his radio alltogether making it unusable even listening to a CD... :) If someone shows up complaining about the interference, you say that we got the amateur radio licence (that's why you need the grandpa) and thell them to get the hell out!!! Then there is nothing that FCC can do either...

2: Wait before he turns the volume up as high as possible and then take your transmitter and feed it with very high level of 30-60 Hz sine wave. This will most likely blow his low frequency speakers out leaving him with no stereo to listen to...

PS: Don't take all the blames from these fuckin "legal" people to personal. Just think that they have no life...

Have Fun...

Also, it could be your browser cache. Hit [Reload].
I had a similar problem with (IIRC) UPS out of Washington state.
My package "sat" in Salt Lake City for a day or two. Ultimately
it was on my porch whilst my browser said "Salt Lake City".
doooh! I did a [Reload] and then saw all the routing updates
past Salt Lake City: depart SLC, arrive/depart Grand Junction,
arrive/out_for_delivery Gunnison.

It's the web designer's fault in such a case. The page should be
tagged as non-cache'able -- yielding a fresh load on each view.
I remember emailing webmaster@ for that instance, and I remember
getting back a non-specific/non-commital reply.

Now that I'm on DSL, I cache Very Little in my browsers. HI!HI!

I'm still new in regards to radio, but had a couple questions
regarding equipment. I've seen some info about pre-amps, and was
wondering if this is just a low-power transmitter that "should" have
an amp between it and the antenna. Is the preamp basically everything
before the power amplifier? If not, where am I mistaken?

Thanks in advance!
Dave

Right, my real objective is not to build a transmitter, but rather, to
stop
the noise, you are right. So, I have 2 options: to continue hearing
the noise all day long, to be a prisoner in my own house (I wonder if
in prison the prisoners have to close their windows in their
cells...), or to go to a real prison to find it out....
It seems to me it's the same option, just changing the name.

Meantime, as I wrote, I'm using from time to time a mini-bug, very
effective...

The term "preamp" (short for preamplifier) is used to describe an amplifier put at the input to a receiver. It's not used for transmitting.

When used with a modern receiver, they often do more harm than good, by generating spurious signals while not improving the signal to noise ratio. One of the few places where they are useful is when mounted at the antenna in a VHF or UHF system when there's significant loss in the feedline between the antenna and receiver.

There are preamps, and there are preamps.
In general, a preamp is used to amplify a Very Low Level signal
up to "general, utility" levels.

E.g.: A mic preamp is used to amplify the Very Low Level signal
of a microphone up to a level where the audio circuits can
better modify and/or filter it. Or, a rcvr preamp is used at the
front of a receiver's antenna input to get the rf input up to a level
where the signal(s) can better be mixed, filtered, or modified.
There are many considerations in the design of a preamp -- but
foremost, maybe, is the design for low noise due to the fact
that these signals do not stand very tall over whatever noise
exist in the system.

Preamps may be external or internal. I.e., a mic preamp could
be found in the base of the microphone, on the cable, or in the
device (transmitter, P.A., etc.) to which the mic is connected.
Same-o for a rcvr preamp: It could be mounted up at the antenna,
somewhere in-line in the transmission line, or inside the receiver.

Dave,

Both Roy and Jonesy are right. As Jonesy says, there are all sorts of preamps. But generally, in a radio context, with no other qualifiers, we are talking about recieve preamps, which Roy assumed.

Roy (who by the way happens to be one of the giants in this business) mentioned that a receive preamp is rarely a good thing. It's easy to get talked out of believing this without some explanation.

What happens is this. There is atmospheric noise. This noise decreases with increasing frequency. If a signal is below the noise, it's below the noise. No amount of amplification is going to help, because you will amplify the noise just as much as the signal. Now, gain is easy to come by at low frequencies, but it gets harder to get at higher frequencies. At HF (typically we mean below 30 MHz), even the cheapest receiver has enough gain to hear the atmospheric noise, and won't be helped with a preamp.

You can run a simple test. Unplug your antenna and turn the volume up until you hear the whooshing sound. (FM doesn't count here - only CW or SSB - FM is a slightly different problem). Now, plug the antenna in. Did the noise go up? If so, then a preamp won't help. Your receiver can already hear the noise, so amplifying it more will do no good. While the need, or lack thereof, holds true for FM as well, the test doesn't work for FM because of the nature of the FM detector.

But wait, there's more. As Roy mentioned, they can do more harm than good. What happens is that in your receiver there are all sorts of nonlinear stages, some intentionally, some because nothing is perfect. When a strong signal gets in, these stages are driven to their nonlinear ranges, and generate other signals, or often, simply more noise. Well, there are always some other signals getting in, by making them stronger, the preamp makes this problem worse. And since the preamp amplified the noise as much as the signal, and now added noise, the volume out of the speaker may have gotten louder, but the signal you want to listen to has gotten harder to hear.

Now, as you go up in frequency, a number of things change. First, the atmospheric noise goes down, so you can make use of more gain. Meanwhile, transistors don't work as well, so that gain is harder to come by. To top it off, the internal noise of the amplifiers and so forth increases. In addition to all this, all feedlines have loss, and those losses increase as

you go up in frequency. At UHF you need to move to very expensive feedline to avoid loosing most of your signal. So at the higher frequencies, a preamp can be useful, especially if it can be placed up on the tower, ahead of the feedline. This way the signal can be amplified above the noise level of the circuitry before it has been attenuated down into the mud by the feedline.

So basically, for HF a preamp is almost never a good idea. For VHF, it can be useful for some special situations, especially if you have an older receiver. For UHF, it can be handy if you have a need for a longer feedline and can't afford the gold plated stuff. For microwave, you almost always need a preamp.

Hope this helps

..

A few more details might be necessary, like 'how much rig?', 'how much battery available?' and the eternal 'how much money?'.

There are some nice, multiband rigs that do HF, VHF and UHF. If the Corps is sending the volunteer someplace where VHF and UHF aren't used there's not much point in getting that capability, but in some places having VHF/UHF used by the local gov't UHF/VHF capability, even 'bootlegged,' could save someone's life.

Yaesu has a HF/VHF/UHF rig designed for low power use,
The FT-817 http://tinyurl.com/wsat

Icom has an HF low power rig:
Icom IC-703 http://www.icom.co.jp/world/info/ic-703/index.html

Low power could be hard to get through with, if there is power from a vehicle battery or similar a 100 watt rig could be used,
http://www.icomamerica.com/products/amateur/706mkIIg/
I have a Yaesu FT-857D in my vehilce, http://tinyurl.com/vkp3

and these are all backpack/mobile radios, a little more rugged than normal. There are other manufacturers, these I have experience with.

I said 'bootlegged' meaning that there are ways to remove the amateur band transmit frequency limits on pretty much all these radios, a radio sold in America has the American limits, German radios have German limits, if you're out in the jungle or in some small, remote village the laws and their enforcement may be different and the local authority might actually appreciate another communiucation point in their jurisdiction (spoken from personal experience) but be certain.

A good antenna is essential, even the best radio is junk without a good antenna. Good antennas don't have to be expensive, they can be made from wire, it would be very valuable to check in to that as well.

That's all I can say right now, supper's waiting,
Galen, W8LNA

Oh yeah, dusty.

Take a few plastic bags big enough to keep the radio in when you're not using it. The radio will need ventilation when being used, especially in hot places. I've used large Tupperware type containers in snowy and rainy places to keep rigs dry, it'd work for dust and critters.

Humid: If it's too wet, it's too wet. Sometimes letting the radio warm up will drive out moisture, unless it's really hot and humid.

Ok, gotta eat,

Do you have a schematic of your transmitter you could put up somewhere ?
That would help with varying the frequency.

Just making more noise just doubles the noise for everybody, including
yourself. Notwithstanding you'd be sinking below their level,
classiness-wise.

> PS: Don't take the blames of these fuckin "legal" people to personal. Just
> think that they have no life...

Speaking of having no life!

Talk to the people - they might not even know you can hear it - they might
have hearing loss, from listening to it too loud. If so, you could offer
to build them a visible level meter that lights a red light when it's
too loud.

Who knows? They might be grateful!

Good Luck!
Rich

I totally agree. I had a guitar shipped to
me from San Diego (to Alturas, CA)
by FedEx Ground, the shipper's choice.

I watched it move around California for
several days, and then it got stuck in
Reno, NV. A few days later, I got a
notice in my mailbox, that a package
was waiting for me at the Post Office.
FedEx had *mailed* it to me from Reno!!

When I complained, I was told that they
reserved the right to *mail* a Ground
shipment to a "remote" destination!!

Just don't use "Ground".

> about the same effect.
>
If in fact, the man is ill, that exacerbates the disservice you'd
be doing both to him, his family, the neighbors, and yourself by
simply making jamming noises. That's the response of a spoiled 2-
year-old brat.

It's not your responsibility to help him with his mental problems,
but the adult thing to do on your part would be to be civilized
about it - if you can't talk to the guy in a civilized fashion,
find some neutral third party, maybe a clergyman or something.

If he's doing violence against his wife, sadly, it's her
responsibility to charge the guy with battery and make it stick -
it's irrelevant how sick a person is, they "should" still be
accountable for their actions.

And violating noise ordinances is actionable. If talking to
him is ineffective, then file a formal complaint, and if it
doesn't do any good, then file another, and keep it up
until "they" do something about it. If a couple of years
go by, and you have documentation of being blown off, then
go to the attorney general and sue the pants off of everyone
involved.

If it really comes to that, you might have to hire somebody with credentials to come out with a sound level meter - but document, document, document. Leave a paper trail.

Of course, don't do any of this crap if in fact you know that you're wrong and are simply overreacting to normal neighbor noise.

Good Luck!
Rich

From: Gary Schafer <gaschafer@comcast.net>
Message-ID: <m7dvk050r8cs6n78tnhkd7gjq995vtaqru@4ax.com>
Source record: 23121

Well Chris, you got a lot of good advice and some completely wrong advice. Funny thing is nobody really answered your question!

I don't know where the CB guys get their power ratings for their amps but the one that you list is not a correct rating unless the amp is very deficient.

A LINEAR amplifier that is capable of 200 watts PEP on SSB should also be capable of 200 watts PEP on AM. Since a properly modulated AM signal has a PEP of 4 times the carrier power (as explained by some others), the carrier of that amp should be only 50 watts.

You need to use a PEP watt meter to see the peak envelope power (PEP). A regular watt meter will not follow the modulation peaks. A regular watt meter should stand still with modulation. It may wiggle a little but not much. If it "swings" way up then you are over modulating (also explained by others).

An AM signal with 50 watts of carrier has 25 watts total average audio power associated with it for 100% modulation. 12 1/2 watts in each side band. This gives you 200 watts peak envelope power (PEP) at full modulation.

At first glance it may not seem right as 50 watts plus 25 watts equals 75 watts. So where does the 200 watts come from? Read on.

By the way the carrier power remains constant in a properly modulated AM transmitter. It does not change with modulation. There are modulation schemes that do vary the carrier power along with the audio but not common as to this discussion.

If you look at an AM signal on a scope it looks as though the carrier is changing, going down to zero and up to twice the level. What you are seeing is the composite voltage from all three signals (carrier and 2 side bands) combined.

Back to the PEP. The carrier power remains constant and the audio power is converted into RF signals that appear on either side of the carrier frequency. This "side band power" from the audio is independent of the carrier. You can eliminate the carrier and you have "double side band suppressed carrier". Eliminate one of the side bands and you have a single side band signal.

Because the amplifier must handle three separate signals at the same time (lower side band, carrier and upper side band) it must be capable of the maximum sum of all the signals present.

In determining PEP you can not directly add powers together. As above, 50 watts of carrier plus 12 1/2 watts in each side band would seem to add up to 75 watts total power. But you must first add the voltages from all 3 signals together first. Then calculate what the power is.

One way to do this is at the 50 ohm antenna line impedance.
Where E = rms voltage. R = ohms. P = average power.

To find the voltage E = square root of PxR. So 50 watts across 50 ohms will produce: 50x50 = 2500. Square root of 2500 = 50 volts rms. Now for the side band powers: 12.5 watts x 50 ohms = 625. Square root of 625 = 25=volts. The same calculation is done for the other side band. We get another 25 volts from it. Now if we add these 3 voltages together 50 + 25 + 25 we have a total of 100 volts on the antenna line at peak modulation levels.

To find the peak envelop power we calculate the power by P=E squared /R.
So 100 x 100 = 10000 divided by 50 ohms, (the line impedance) = 200 watts!

This is how you convert average power to PEP. I say average power because RMS power is really a misnomer. There is no such thing as RMS power as so many commonly refer to. It is really AVERAGE power. It is derived from RMS current and RMS voltage but what you get when you multiply RMS voltage by RMS current or resistance is an AVERAGE value, not an RMS value.
This may seem trivial but it becomes important when trying to convert from one form to another. Using the wrong notation can give you wrong answers.

As to the above, the average voltage or current of a sine wave is 50% of the peak.
The rms value of a sine wave is .707 of the peak voltage or current. If you multiply .707 (rms voltage) by .707 (rms current) you get .5 or 50%.
This is AVERAGE. It is no longer an rms value.

By the way, the definition of peak envelope power (PEP) is: "The average power contained in one RF cycle at the crest of the modulation envelope". (note that the definition says "AVERAGE power" not RMS power)

If you think about it for awhile, keeping in mind how we added the voltages together to find the PEP, and also keep in mind that the audio signals have been turned into RF signals, you will better understand what PEP really is.

Here is another thing to consider: With just a carrier and no modulation, the PEP power is the same as the average power of that signal.

With only an SSB signal in the amp, the amp does not need to deal with any composite signal. No voltages to add together. Only one signal to

amplify so that one signal can occupy the full power of the amp. Thus
that 200 watt PEP amp can now handle full 200 watts of side band power
rather than 12 1/2 watts for one side band with the AM signal.

Hope this helps

Hi All;
You never know when you'll need a pot for restoration purposes:-)
Most on these are brand new but NOS, never been soldered on.
There are:
9-doubles marked Philco, 750 & 15K ohms.
21-Singles marked Philco, 750 ohms.
1- Used 500 ohm.
2-nos, 2-section 1.2Meg ea.
2-nos, 2-section, 2.5 & 2.2 Meg ea.
1-nos 100K
2-nos, 2-section 23K ea.
1-nos 5k.
I hope someone can use these, shame to let them go to the "bone Yard":-(

2690. FETs: measuring Vgs(off)

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-09-21 15:32:14 UTC
From: Paul Burridge <pb@notthisbit.osiris1.co.uk>
Message-ID: <0th0l094c5c3f8mk0ikgcr4dp3uglb4umv@4ax.com>
Source record: 23124
Cross-posted to: rec.radio.amateur.homebrew,sci.electronics.design

Hi guys,

I saw in Malvino's Electronic Principles that it is stated that Idss and gfs (the transconductance/gain) are easy to measure, whereas Vgs(off) is not and that manufacturers calculate it from this formula (hope I've remembered it right)

Vgs(off) = -2*Idss/gfs

I've just checked out this assertion by measuring Vgs - v - Id for a bunch of assorted FETs and found that I could easily establish the pinch off voltage to within about 0.1V either way. Contrary to what the book says, I personally have found it a simple matter to measure Vgs(off). So why do they make out it's a big deal?

Hello Paul,
Vgs_off seems to be often specified at Id=1nA. The measurement
at such low current levels takes a lot of time and it requires a
very clean test fixture.

How have you measured at exactly Id = 1nA +/-0.1nA ?

Best Regards,
Helmut

Hi Helmut,

Is it 1nA? I thought it was 5. No matter.
Yes, I'd expected someone to point out that the "negligible current"
point was the likely problem area. I can't honestly say that I have,
because my DVM drops out at 0.01mA! However, in the context of the
wide spread of parameters one encounters with FETs., I'm pretty
confident my 'drop-out' zone for current measurement is not too far
off the mark. But you've answered my question and as ever I'm grateful
to you for that.
I actually found it more difficult measuring Id as Vgs approached
zero. The negative tempco of these devices made that part more
challenging. Fortunately I've got a 'peak-hold' button on my meter and
by only connecting the drain circuit for a fraction of a second I was
able to get what I believe to be a valid reading. Certainly good
enough given the cushion one has to build into FET circuit design as a
matter of course, anyway.

>A typical datasheet:
>http://www.fairchildsemi.com/ds/J3/J310.pdf

Ah, I see they use a 300uS pulse, presumably to keep the device
temperature down?

Regards,

p.

2693. Battery question

So, with not too much fault you may use a VTVM as load and see which
voltage it reads....

International Rectifier has a white-paper on characterizing MOSFET's --
kind of like comparing a Caterpillar D-9 to a bicycle -- but all of the
standardized measurement methods are described in detail.

If you have to measure nano, pico or femto -- Bob Pease had this interesting
article on the NatSemi website about a half-dozen years ago:

http://www.national.com/rap/Story/0,1562,5,00.html

Turn it to voltage.
Most meters (the four I've measured) have a 1Mohm or so input impedance
on the 200mv range.
This is 200nA full scale.
Probably best to do the test twice, with the meter leads reversed though.

2699. Had to fix my TS440SAT, cracked solder joints on a transistor

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-09-22 02:45:46 UTC
From: Robert Casey <wa2ise@ix.netcom.com>
Message-ID: <4150E757.6070601@ix.netcom.com>
Source record: 23133

Was Q37's leads to the IF circuit board. Somehow it
developed circular cracks in the solder joint from
the leads to the board. It kept the rig from going
into transmit. It was just a control line level
shifter or inverter.

Oddly enough I had just finished installing a new
wire dipole strung between trees on my house's
quarter acre lot. Something vaguely resembling a
80 meter dipole with a W2AU balun at the feedpoint.
I thought that I somehow toasted
the xmit part of the rig with a bad antenna, but the
rig has self protection circuits. I don't think bad
solder joints on a control line transistor would be
caused by a new antenna.... :-)

> Probably best to do the test twice, with the meter leads reversed though.

The multimeters on my bench have infinite input impedance on the 200mV
scale, although some let you turn on an internal resistor. We can use
external 10M or 100M if we like, which gives 1pA and 0.1pA measurement
resolution with a 4.5-digit meter.

The relevant "subthreshold" formula is Id = k e^(Vgs - Vt), which is
an exponential equation that clearly shows there's no sudden threshold
for FET current => negligible. Paul can take a look at AoE page 123,
and observe the measured gate-voltage to drain current relationship for
a typical MOSFET, which shows the standard smooth 100 or 150mV/decade
(p or n-type) gate-voltage change over a wide 7-decade current range.

1 or 5nA makes no difference? Nope, that apparently small detail makes
a predictably large 70 to 100mV difference. One must pay attention to
the specifications in this matter, 1nA, 1uA, whatever - it's a big deal.

BTW, as I've pointed out several times, power MOSFET spice models are
completely wrong in this region, just forget considering their results.

2703. Re: Not homebrew -- but can u recommend a rig for Peace Corps volunteer

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-09-22 06:26:41 UTC
From: The Eternal Squire <eternalsquire@comcast.net>
Message-ID: <BcmdnQ9pAea_hszcRVn-oA@comcast.com>
Source record: 23137

John,

May I suggest a few points of prudence for you to consider?

1) Are you transmitting or simply intending to receive?

The former will most definitely require both a General Class license or higher in this country, and either a reciprocal license, local license, government permit, or a joint recognition treaty with the host country that gives you the equivalent of General priviledges over there.

Keep in mind also that you will be limited to the priviledges of the host country which extends these priviledges to you.

Even the possession of a receiver may require a license in the host country. There could be several reasons for this: authoritarian state where individual rights are far from paramount in the eyes of thier law, free state (UK) that takes revenue from receiver licenses, or a state where all communications are nationalized and thus even receivers are considered government property.

2) Assuming you are transceiving, for what purpose do you intend to use the transceiver for?

If you are intending to contact relatives and home office stateside as third parties, you cannot use the amateur bands for this purposes, as this is considered a business communication. There are countries having even stricter third party restrictions than we have, and you would of course need to consider the laws of both countries prior to originating or handling such traffic.

You would be well advised to invest in a satellite phone instead.

3) If you are being sent to a place where the politics are at best volatile and at worst violent, the possession of amateur gear could be misconstrued by anyone from government paramilitaries to insurgent terrorists in the host country as equipment in support of espionage.

The discovery of such gear in your possession could place your life in even worse danger than your status as a US Peace Corp Volunteer normally would.

This is another extremely good reason to consider a satellite phone instead.

4) Unless you can arrange for the item to be conveyed via "diplomatic pouch", be prepared to pay a heavy customs duty to the host country. The US State Department is usually quite cooperative with arranging diplomatic immunity for conveyance of items necessary to the mission of

the US Peace Corp, though this is usually more along the category of medications for humanitarian purposes. Consult with your superior for more details.

5) If you are still determined, you should next consider tradeoffs in reliability, portability, and rugged construction:

a) In terms of reliability, well constructed all-tube SSB/morse gear is the gold standard for taking both physical and electrical abuse in unknown situations, and can invariably run off of 50 or 60 hertz mains across a wide range of input AC voltage level - 117 volts gear can generally operate from 90 Volts minimum to 130 maximum.

Collins gear circa 1950-1970 would be eminently suitable for semipermanent stations, and you can still see complete Collins transcievers in working condition for under $1000. US military surplus all-band SSB transcievers of similar construction to Collins may also prove suitable.

The main disadvantages of this approach are: (1) you would need access to a dedicate power grid or at the very least, or at least 3 watts of power inverted from several paralled car batteries for every watt of power you intend to transmit. A 1000 Watt power inverter would be suitable for 300 Watts transmitter output. (2) due to the relative fragility of vaccum tubes, you should take at least 2 spares of every tube used by your transciever, and at least 3 extra sets of final amplifier tubes.

b) Well constructed hybrid transistor/tube gear is the next best with respect to physical abuse, but it is generally restricted in terms of the variety of power supplies which can be adapted to it. It is much more sensitive to power supply frequency, and a sag or surge much outside 10% of the 117 volts input could even damage your gear.

The later model Heathkits, Yaesus, and Galaxies (I cut my teeth on a Galaxy V Mark II during childhood), are all very good examples.

c) All-semiconductor gear such as from Icom, has the advantage of being miniature, highly sensitive with outstanding selectivity for weak signal work, quite flexible to operate, and can be run directly off of a car battery, generator, or solar panels without need of inversion.

The main disadvantage is the exquisite sensitivity of modern semiconductors to dirty power, I recommend very much against running any all-semiconductor gear from a third-world power grid. Another major disadvantage is the lack of user-servicable parts... if you intend to go this route, bring TWO of them with you.

6) Don't forget other important station accessories, such as low pass filter output, output balun, transmatch, and SWR meter. Old style wraparound headphones are especially important for operator comfort. Expect to spend another $1000 to $1500 on the accessories allow, if you want rugged and top of the line accessories from the best names.

7) Paralleled inverted vee antennas cut for the bands you desire to
operate will give you the most flexible compromise between
bandswitching, local, and intercontinental operation. Consult the
ARRL Antenna Book for details.

Good luck,

The Eternal Squire

Just curious, had the rig ever been used mobile? I had my TS690 mobile for a while and saw how badly it shook around and pulled it out and put it back into home use, sitting on a nice and stable table with no astronaut crippling g-loads. I like the rig too much to have kept beating it up in the truck. I bought a much smaller (thus easier to get solid mounting) Yaesu 857 for the truck and it seems to fair much better than the large (heavy) Kenwood did in that environment...

While I never put it on the air, I did experiment with a wideband FM
transmitter coupled to an AVR chip generating a long fast PN sequence.
Worked pretty much as you'd expect.
Broadband jammers do take a lot of power to be effective.
Everything's permissable, as long as you don't radiate. :)

I admit I never thought of doing it this way. Incidentally, talking of
very low currents, on P.170 you've reproduced a picture of a static
damaged MOSFET. I assume from the commentary that this one was totally
trashed, but you've stated before that these devices can be partially
blown and still function, albeit to an impaired extent. Could one
feasibly measure any such 'minor damage' (through static) by checking
for picoamp range current leakage across the insulating layer?

I got it used, so I don't know its early history. It was nice
and clean, so I suspect it had not gone mobile. I think that the
circuit board may have been a tad bit short of solder when they
wave soldered it at the factory. Not by much though. It has
always been a home rig when I've had it.

One annoying thing with the service manual is that it has the
schematics of each board, but no diagram of the interconnections
between boards. Other than a high level system block diagram.
I was going to try to back track the "on air" LED to find why
if failed to light, but couldn't find it in the service manual.
Major surgery would be required to trace it out by hand, so
I took another approach. That was to see how far the control
line "RL" signal got thru the various transistors. That's when
I found the bad solder joints.

2714. New program "Not a Trap"

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-09-22 21:41:04 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>

Source record: 22998

Extract from program notes.

Program Name: NOTATRAP.exe Author: R.J.Edwards G4FGQ

A TWO-BAND ANTENNA WIRE LOADED WITH AN L & C PARALLEL-TUNED CIRCUIT

The LC parallel-tuned circuit is constructed exactly like an antenna trap. It
is located in the antenna wire and used as L or C loading at 2 other resonant
frequencies. Parallel-tuned circuits have a reactive impedance on either side
of resonance. On the low frequency side there is a +ve inductive reactance. On
the high frequency side there is a -ve capacitative reactance.

The purpose of the LC loading components is to detune the antenna wire from
its natural 1/4-wave resonant frequency. When the loading circuit is behaving
as an inductance the antenna resonant frequency is reduced. When the loading
circuit is behaving as a capacitor the antenna resonant frequency is increased.
The pair of resonant frequencies depend on the LC ratio, on wire length, and
on the location of the LC loading circuit along the wire.

For a given loading location along the wire and a given pair of resonant freq-
encies this program calculates the L and C loading-component values. The pair
of frequencies lie above and below the unloaded resonant frequency of the wire.
The LC circuit behaves as an ordinary trap at its own resonant frequency which,
by experiment, can sometimes be arranged to fall into a third amateur band. But
to calculate such a fortunate coincidence is beyond my elderly patience.

The program has a built in signal source which generates a wide-ranging
testing frequency which can be used to 'measure' the input impedance of the
antenna versus frequency, checking resonant frequencies and other antenna
characteristics.

Download program NOTATRAP from website below and run immediately.

There is this schematic of a tracking transmitter at Antoon's website at UOguelph. It puts out a pulse of RF every second or three. What you do is change the capacitor in the pulse gen so that it puts out pulses at high audio freqs. If the pulses are sharp, it will be heard over many channels of the band.

Another jammer is a buzzer with a dipole antenna of two wires a few feet long. But this jammer makes noise and is easily discovered.

All points noted - I am aware of the limitations of the things,
but.....

4 of them in // should be capable of 200 watts output - yep, not QRO
but a 3db improvemnet over the 100 watts of the typical modern HF
radio. The G2DAF circuit looks interesting - simple, robust, forgiving
- and VK4YE's work on matching input impedance to a modern 50R HF
radio sems to solve the drive mismatch impedance problem.

So, will stuff around and experiment - it should be a good junkbox
project - as a monobander would be relatively simple to construct -
dirt cheap, a learning experience, and as numerous people have noted,
there are THOUSANDS of 807's in junk boxes all round the world, just
eagerly waiting to be used again.......

Thanks to all who posted,

Andrew VK3BFA

> into a third amateur band. But to calculate such a fortunate
> coincidence is beyond my elderly patience.

This comment and some test run of "Not a Trap" intrigued me. I own a 9m fiberglass fishing rod, which I can now transform in a two-band no-tune antenna (ie 40m and 20m). Adding a third band would be really cool.

(I originally thought of using your VERTLOAD program to build a two-band vertical, where the coil behaves as a RF high-impedance and the lower "half" of the radiator is 1/4 wavelength at a higher frequency.)

From a software point of view a little auto-optimization is needed, which I am about to describe. I would be most grateful if you can either write a notatrap2 or show me the way to produce such an optimization software (I need formulas for computing L and C :-)).

The algorithm.

The user enters: maximum available height, wire diameter, minimum and maximum frequency, as now.
Then, instead of L-C height, the user enters the desired "bonus" frequency. The order of magnitude of frequencies must obviously be in increasing order:
- minimum (ie 7.030 MHz)
- maximum (ie 14.060 MHz)
- bonus (ie 28.060 MHz)

Given the 1/4 wavelength at the bonus frequency, the software computes the L-C height, which is fixed. Then the optimization begins.

Starting from the maximum allowable height the software reduces step-by-step (user defined?) the lenght of the upper part. At each step the following are recomputed:
- L for minimum freq
- C for maximum freq
- LC self-resonant freq
If the latter is equal/close enough (user defined?) to the bonus frequency, optimization stops and results are shown.

Then user can shorten/lengthen the rod in order to fine tune the bonus point of resonance.

Did I miss something in the algorithm?

==========
Hello Paolo,

The resonannt frequency of the LC tuned circuit, the trap, is calculated by the program and displayed on the screen.

The only way of putting the trap's resonant frequency into an amateur band is to experiment and vary the wire overall length, and/or the location of of the trap along the wire until you have it where you want it.

I think it is impossible to have a program which allows all three frequencies to be entered, plus the lengths of the two wires, which then calculates the values of L and C. There are too many variables. And before writing the program all the simultaneous equations have to be worked out and solved using pencil and paper.

The program is really required to simulate the actions of somebody who keeps pruning both wires, climbs up and down the ladder, and varies the values of L and C hundreds of times. That is the best optimisation procedure. ;o)

Another disadvantage - the length of wire from the transmitter end of the wire to the location of the trap will NOT be a 1/4-wavelength at the trap resonant frequency as is usual for trapped antennas.

You will always need a tuner because the antenna's feedpoint impedance varies so much between one band and another. It is not sufficient just to have the antenna at resonance.

I'd stay away from tube gear. The switches and tube sockets may be intermittend after all these years and it's impossible finding some of the replacement tubes. In addition, the analog local oscillators will drift in the heat and humidity.

I'd recommend the latest generation of transceivers that emplou DDS/PLL synthesizers. If you require 100watt transmit power, I'd look at the Yaesu FT-897 or FT-857. They have moderate receive current consumption and the 897 will run from internal batteries (with 20 watts output). In addition, they operate 6 M, 2M and 70 cM.

If 10 watts will suffice. I'd look at the ICOM IC-703.

Put them through their paces before you travel with them. The 703 has problems with the driver stages failing; get the bugs fixed under warranty before traveling.

These are Amateur radio transceivers and I'm assuming you have a license and will get a reciprocal license for the country you intend to operate from.

Which country will you be working in? Good luck.

Regard's

Brian, It constantly occurs to me that but for the common English Language
our brief communication would very likely not have taken place. I am
certainly not bragging about the English Language. It's just that I realise
I am very fortunate in having being born into it. I have a smattering of
French but by chance I have never visited that sensible country to improve
upon it. The English are lazy.

To ease the present terrible state of international relations (Armageddon is
upon us) should not the Western world introduce Chinese and Hindu into their
primary schools as next in importance to arithmetic?

Arithmetic, the pure language of logic, such as Wavelength = 300 /
Frequency, of course, predominates.

Source record: 23018

as compared to my home radios/stereos?

All--

Have wondered for years why this is so--almost w/o exception,
on both AM/FM. On the car NGs, it was suggested that my house was blocking
signals, and that the metallic car acted as a big antenna. Neither seems
plausible, as my car next to the shop radio (which is terrible) still gets
good reception, and that if the metal in a car were so good, you wouldn't
need a car antenna.
I'm thinking it's the actual electronics. Any
opinions/explanations?

Car radios (at least back in the tube era) were generally superior
to most inexpensive home radios. They included a tuned RF
stage which gave them the extra ooomph. The tube auto radios
had the antenna as part of the tuned circuit (coupled to the
high impedance point of the RF stage), so they worked somewhat
like a tuned active antenna.

Behold, Proctologically Violatedï¿½ï¿½ signalled from keyed 4-1000A filament:

> as compared to my home radios/stereos?

All car radio's use an actual antenna to receive signals. Many home
stereo's don't even have a connection for an external antenna
anymore....they're mostly just vapourware.

Hello all,

I have the schematic for this altoids project but there is no parts list that I can find. I can build them but getting parts is different. My last project was a rockmite 20. I was successful but this project is only by schematic. If anyone knows anything about this thing, can you help me out. I have a feeling once I get started, I may have quite a few questions. Is a relay a relay a relay? K1 is a relay but does it have to be what he suggests? I will probably get that relay but I am trying to learn as well. Thanks so much.

Since cars drive through all the poor reception areas as well as good places, there is a strong incentive to build their radios to have good performance. These days the weak-signal performance of the AM side of car radios is degraded, since RF noise levels are so high. It's cheaper to degrade the radio than to further suppress the noise the car makes - and anyway power lines, etc., are pretty noisy. But the FM sections are generally very good.

The ordinary plastic-box home radio or all-in-one system has a VERY cheap radio. Your expensive hi-fi probably has a good FM section, but most are very poor on AM.

It's all a matter of design and perception of what the listener will tolerate. No sense building a wondrous radio if most buyers don't care and wouldn't want to pay what it would cost..

2740. Getting RF amp stable

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-09-26 19:11:07 UTC
From: meara.london@virgin.net
Message-ID: <22f6e3ee.0409261111.60130e9e@posting.google.com>
Source record: 23023

I've built a little RF amp (for 20 meters) using a single MTP3055V
MOSFET.
Class AB, binocular core RF transformer in the output. I drive it
with
a homebrew 20 meter DSB rig.

Here is the problem: The amp works fine IF I take the low pass filter
out of the circuit. I'm using a groundplane antenna with a T network
tuner.
I can adjust it to make it look like 50 ohms. Without the low pass
filter,
I get a very nice clean output (looks good on a scope, and SWR is low,
so I don't think it is putting out spurs or harmonics).

But if I include the LP filter in the circuit, the amp takes off,
turning
into an 18 Mhz oscillator!

I checked the filter with a sig generator. The cutoff freq is where
it is
supposed to be.

I've had this kind of problem before, with other amps.

Any suggestions?

All relays are not the same. If the adapter is the one shown at
http://www.qsl.net/n5ib/page2.html
then it is a 2 pole 12 volt relay. You should use the one he
used, until you are comfortable that you know enough to
figure out a different one. A different relay is a good idea,
as the circuit uses power from the htx 10 and the relay
consumes most of it. A different relay that uses less power
would be a better choice. The one on the web site uses
.72 watts.

But, since you did not post a reference to the schematic,
we can only guess that it is the one at the site mentioned
above. Next time, post a url where we can see the schematic
you are using.

On your question about resistors - 1/4 watt will be fine.

Another reason was the lower IF -- generally 265 kHz vs. the 455 kHz used in
home sets. This allowed a more selective IF -- smaller bandwidth for the same
Q -- so the adjacent channel interference was cut dow. Some MW [BCB] DXers
would use car radios set up for home use for just that reason.

From: nx7u@arrl.net
Message-ID: <41573489.13520550@news.west.cox.net>
Source record: 23031

Unlike gain, stability is a DC-to-daylight phenomenon.
Meaning...the LPF presents the "Right" impedance to the amp output in the passband, but consider: the LPF is a gross mismatch in the stopband. Evidently the output of the amp is only conditionally stable above the LPF cutoff, and the stopband impedance of the LPF lies in the unstable region.
This kind of thing can be quite common when not considering stability across all possible frequencies that the amp has a gain>1.

Suggestion, try a low pass to the antenna and a highpass to a 50ohm load. then the amp[sees 50 ohms for all loads and also the high pass section will absorb harmonics. The pow pass and the highpass share a common port (the one looking toward the amp). This is documented in EMDRF and other places.

I'd also look at the layout and maybe try loading the drain choke with a resistor in the 40-100ohm range. The choke may be resonant at some nearby frequency.

One of the problems with MOS power FETs is there is substantial drain to gate capacitance and if the gate is not loade or the drain enough results and feedback can be problematic. You can also try loading the gate to ground with a resistor in series with a cap (try 50 ohms and .01uf) or a series combo of 100ohms and .01uf from drain to gate to add negative feedback.

From: The Eternal Squire <eternalsquire@comcast.net>
Message-ID: <CsCdne-ibL8dKsrcRVn-sA@comcast.com>
Source record: 23034

Hi,

I've been playing with a circuit that I believe has some
potential, the lineup is as follows.

I'm turning an 0.5V DC offset, 0.5V audio signal at
1000 hz to modulate an RF 5V VCO where 0V->1Mhz, and 1V->2Mhz
The VCO drives a switched capacitor cell (1000pf) to create a
simulated resistance. This simulated resistance is the top
resistor for a series voltage divider, the bottom resistor
of which is 1M.

I send 20V to the voltage divider, the output of the voltage
divider is sent to a low pass filter to retrieve the audio
signal, in millivolts, with a slight DC component.

```
* C:\Program Files\LTC\SwCADIII\Draft1.asc
R3 N005 0 1e6
C1 N004 N005 1000p
V7 N006 N008 SINE(0.5 0.5 1000)
S4 N003 N004 N002 N001 MYSW
S2 0 N004 N001 N002 MYSW
R2 N001 0 1e12
V1 N003 0 20V
A1 N006 N007 0 0 0 0 N010 0 MODULATOR space=1e6 mark=2.2e6
V2 N007 N008 5V
R1 N009 N005 1000
C2 N009 0 1ï¿½
R4 N008 0 1e12
R5 N002 N010 1000
C3 N002 0 330p
.tran 0 .001 0 .01
.model MYSW SW(Ron=1e-12 Roff=1e12 Vt=1.0 Vh=0)
.backanno
.end
```

There's at least a couple amazing things about this circuit:

1) If I adjust the top frequency in the VCO slightly, I have
a DC reading frequency meter. If I scale the VCO and DC output
correctly I could read 2.100 to 2.150 Mhz reading as .100 to .150
Volts, and so can display frequency digitally without needing the
expense of a frequency counter, only a cheap DMM module.

2) If I place an RF filter between the VCO and the switched
capacitor, I can decide what range of angles I want the 1000hz

audio signal to appear.

For example, if I have a lowpass RC
filter of R=1000 Ohm and C=330 pf, then only that portion of
the 1000 hz signal for a small range of angle surrounding the
negative peak of the input will appear on the output.

If I have use a highpass filter instead, I will eliminate the
entire signal except for the angles surrounding the positive
peak.

3) Suppose I use an arbitrary voice signal instead of the 1000hz
tone. I could use a lowpass filter to eliminate portions of the
signal going above an arbitrary voltage, meaning that I have the
beginnings of an AGC control or noise blanker. I could use a
pass filter to eliminate portions of the signal going below an
arbitrary voltage, meaning that I can eliminate an arbitrary portion
of the noise floor.

The only circuit I am aware of that has properties remotely similar
to this is an FM discriminator, and I think I am going into unknown
territory here...

Opinions?

The Eternal Squire

(yes, I have a call, but I prefer my privacy)

You may have trouble finding one with a pre-amp output, but most
of the new ones have "line level" outputs. That's what many of them
use to drive those gigawatt bass amplifiers, so they can shake the
rust off of their car.

Message-ID: <r1W5d.11304$gG4.878@newsread1.news.pas.earthlink.net>
Source record: 23039

I am looking at a 10 Meter mobile amp with (2) 6KV6A or 6JG6A tubes. I know these are originally sweep tubes. The input SWR is over 3:1 and I'm thinking that a resistor has been replaced by a wire jumper. There is no series resistance or capacitance between the input and tubes. Adding a 25 Ohm resistor drops the input SWR to 1.5:1 or lower. So what kind of power output should I see on AM and SSB without harming the tubes?

Seems like a complicated way to do it, and it will have only the
stability of whatever analog components you're using. Why bother,
when a counter can be as cheap, fewer smaller parts, and have crystal
stability? See also various F to V converters if you really must do
it with analog; I think Jim Williams and Bob Pease have both published
some good work on them.

I'm not exactly certain what you've built - is each 'leg' of the dipole about 19" - in that case you have a half-wave dipole.

The good thing about a half-wave dipole is that the impedance at the centre of the dipole is a good match for your feeder & radio. If you change the length of the dipole 'legs' then you'll get a poor match at a half-wave per leg - but should get a good match again at 3/4 wavelength - but by that time the thing's getting cumbersome.

If you want something like a dipole but with more gain try a single 'quad' element, or maybe a 'slim-jim' type of antenna....

Alternatively a commercial mobile whip (say a 5/8th) with a suitable ground plane might improve things for you - all depends on what you're trying to achieve...

> A 1/2 wave will "get out" better than a 1/4 wave.

Except, of course, for the little detail that Adrian alludes to. Assuming your dipole is 19" on each side, then doubling it to 38" on each side will cause a problem -- the feed point impedance will be wrong. You will need to do some impedance matching in order to get your RF into the antenna in the first place. It's fairly tricky to do that without incurring noticeable loss, but once the RF gets into the antenna, it will work better.

HOWEVER, if you have a dipole whose total length is 19", then doubling it so it is 19" on either side will make it a whale of a lot better. A doublet only 19" long in total is not only too short to resonate, but the feedpoint impedance will prevent most of your RF from ever getting into the antenna in the first place, so the performance of the system will be dismal.

A half-wave dipole, on 2 meters, one 19" on each leg, is a very good antenna, providing you can take the feedline away at approximately right angles to the antenna. Most of the other designs for 2 meters (short of multi-element designs) are actually a little poorer than a dipole except they solve that problem of the feedline coming off at an inconvenient place. Since on FM you want a vertical antenna, a dipole is messy because you usually want the antenna up high so you want the feedline to come up from the bottom. In your case, where you can't get very much height, it may not be much of a problem to bring the feedline out horizontally for a ways.

Now on 2 meters, height is everything. The J-pole Adrian mentions might give you the opportunity to get a little more height, which will make it work a lot better. The J-pole has the feedline coming in at the bottom, just what you want. Although it is mechanically relatively simple to build, some people report that it is very tricky to build right. Others seems to make almost any approximation work well. If you can gain a little more height by building a J-pole, then I would suggest you go ahead and try it. There are all sorts of designs out there, and they are pretty inexpensive to build. But if you are stuck with something close to your window, then then dipole maybe a better deal.

#1 reason is the Antenna. #2 cost is king!

Car = antenna on AM & FM

Home radio = Bar antenna on AM and ? what on FM... Sometimes it is the power cord. Sometimes you have a wire to drape over the lamp shade. The aluminum backing on house insulation can provide some attenuation effect, but I'm sure this is less of a factor...it is the primarily the antenna.

Car radios on FM do not have exceptional selectivity as speculated above. The adjacent channel selectivity is only fair and the systems are made to only use alternate channels in any one market, anyway. When you're between markets and have a weak station 200 KHz away from a strong one that you have trouble. If "they" wanted better performance @ home is could be done, just costs $$. Low IF for reduced BW can be done in any radio, but size and Q and frequency are not independent, so lower freq IF means bigger coils and more "R", so "same Q - lower IF" is not that simple.

Did you hear about that guy who changed his name to "They". Interview on pub radio this weekend.

It must be a couple of decades since IF bandwidth depended on "real" IF
coils and their Q. Since then mechanical [ceramic] filters have set the
bandwidth of essentially all consumer radios known to me. OK there are now
a few high-end DSP-based radios. Those too-narrow IFs in today's AM radios
come from ceramic filters, not low freq IF.

Selectivity is easier for FM since they can use inexpensive ceramic filters
instead of IF transformers. Unfortunately, instead of going a few pennies
more for DECENT filters, they use the cheapest they can get away with.

Did some testing. 6KV6A - 100W carrier, 6JG6A - 75W carrier. It produces up to a 200W unmodulated carrier. I have no idea of PEP since my old Drake meter can't mesure it. It is however, faily accurate for an unmodulated carrier into a dummy load.

Think of it as a switch that turns on when the voltage across it gets high
enough. Used in charging, and abruptly discharging, high-voltage capacitor
banks. See also "ignitron".

A decent car radio in FM isn't anymore selective or sensitive than a
decent home stereo tuner or receiver in FM. The reason a car radio
sounds cleaner on weaker FM stations has more to do with the stereo
mpx circuit. All car radios have a circuit in the mpx circuit that
blends the stereo-to-mono and mono-to-stereo mode. When manually set
in FM mono mode on a home stereo the SNR is better than in stereo mode
on weak stations. The same holds true for an FM car radio. The only
difference is car radios don't have mono switches. Instead, internal
to the FM car tuner is a circuit that blends the stereo/mono mode so
when the car is in motion and signal strength is varying all over the
place the tuner isn't constantly and abruptly switching between stereo
and mono. Also in this blend circuit is an RC time constant that
"smooths" out the blending action. So somewhere a happy medium is
established and a relative slowly changing SNR takes place slow enough
to be unnoticable. In other words, if far enough from a station the
car radio isn't in 100% stereo mode. It's some where between stereo
and mono. If you're right near the broadcast antenna SNR is best as
well as full stereo separation.

2774. KC8AON Iambic Paddle Project

Newsgroup: rec.radio.amateur.homebrew

Hello to all:

I just saw the Iambic paddle project of KC8AON and liked it enough to go buy an enclosure to use in making it.

This is a simple paddle that would be great for a newcomer to amateur radio, and would be just dandy for use while hiking, backpacking, etc.

You can see the details in the August 2004 edition of "Bacon Bits" of the Flying Pigs QRP International Club. Find it at http://www.mpna.com/fpqrp/BB0804.pdf

Message-ID: <_hm6d.119968$Np2.85853@bignews4.bellsouth.net>
Source record: 22959

I built a small audio power amp to drive my computer
speakers. With one channel driven into 8 ohms the PP
voltage measured at 1khz was 24v before clipping.
With both channels driven it was 20v.

I think the formula for power output was ((vpp/sqr 2)**2)/R
which would give me 36W one channel, and 25w per channel with
both driven.
(not bad for a 2n3055/mj2955 pair running at +- 15 volts)

Is my math correct?

Your formula is off by a factor of 4. 24 vpp across 8 ohms = 9 watts.
Sorry 'bout that.

But who cares -- is it loud enough or isn't it?

If you are looking for average power out the formula is E squared/ R
Where E is rms volts. Rms voltage = .707 of peak voltage. Peak voltage
is .5 of PP.

So your power out is around 9 watts.

Bill N2CQR MOHBR wrote:

> But if I include the LP filter in the circuit, the amp takes off,
> turning
> into an 18 Mhz oscillator!

I have found that the best way to build a stable amplifier is
to try and build an oscillator. To build a guaranteed to start
first time, every time oscillator, just try to build a stable
amplifier :-)

Follow good HF/VHF practice with the circuit layout.

Negative feedback can sometimes help (or make the problem worse).

Pay careful attention to power supply decoupling. The very
high LF gain of RF transistors can cause parasitic oscillation
at the resonant frequency of an L/C or R/C decoupling circuit.

Try the usual parasitic suppression tricks. A low value resistor
or ferrite bead in series with the FET gate. A ferrite bead
in series with the FET drain. A resistor in parallel with the
drain load inductor or transformer, as suggested by Allison.

Sometimes it can be easier and faster to start again with
a different layout than to debug a 'bad' circuit.

I built a portable 2m J-Pole out of 3/4" copper pipe.

When I want to play on 2m I just drag it out of the garage, and jam it in the ground. It's less than 10 feet tall, yet with it and my FT2600 at half power (25w-30w) I have had QSO's with hams on repeater systems almost 100 miles away. I turn the power all the way down to a few watts when working local repeater systems too.

Go here: http://archimedes.galilei.com/raiar/cactus.html

You don't say you're building this for UHF/VHF, so I am making an assumption.

A great vertical for 15-40m can be found on the W2IK website. And it is portable.

Use K1 as specified, and order 1/4w resistors.

K1 is Digikey Part 255-1002-ND - Mouser may have them for less $$ (Aromat TQ2E-12V)

For NPN's use 2N2222A or equiv. (TP2222, PN2222A, etc)

For PNP I'd use 2N2907's as they are a little more sturdy than the 2N3906

There is no side tone generated with this mod.

The article explains how to determine speaker impedance. Not how to measure amplifier power.

My point was "how do you know" the OP did not use an 8 ohm resistor for his power measurements. He did not say.

The common notation for power is E squared /R.

E squared /Z will not give you the correct answer unless Z is purely resistive.

You can not just measure voltage across a complex impedance and determine power. It is more complicated. You must then also know the phase angle that the reactance presents along with the resistance.

Exactly my point - if he used the speaker and not an 8-ohm non inductive
resistor as the load

Yep. If everything works except the tuning knob, it sounds like you have a burned-out incandescent lamp in the rotary optical encoder for that knob. Pull the cover and look at the backside of the rotary encoder on the keyboard PCB with the analyzer running. If you don't see a glowing light bulb, that's the problem.

These are the smallest light bulbs I've ever seen. I once tried to substitute an LED for one of these bulbs, but didn't have any luck. If that's the problem, it may be tough to find a replacement. Hobby shop, maybe? Jim Yanik (formerly of Tek) may have a pointer or two if he sees your post.

Why do it the hard way. Use a bidirectional coupler made for the frequency range and power level of the amp such as the Bird 4266(1500 Watts). Then you can measure power, SWR or hook up your counter, oscope, or spectrum analyzer etc. without fear of destroying them. It gives 30 dB isolation from the line and is flat in frequency response (plus/minus 0.5 dB or less 1.5 to 40 Mhz measured here.)

2799. 18nH Inductor

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-09-30 19:56:34 UTC
From: Joe <nuisancewildlife@nospamearthlink.net>
Message-ID: <SxZ6d.5576$ls6.2629@newsread3.news.atl.earthlink.net>

I have been searching the catalogs for an 18nanohenry inductor to use in conjunction with a Radiotronix RCR-433-RP Receiver and transmitter pair for a remote control I am working on. Radiotronix has an app note that shows this inductor used with a couple of 8.2pf caps to get good reception/transmission for their modules.

I have been unable to find a source other than surface mount parts. Does anyone know of a source for this size inductor, or know the formula that I would use to wind my own?

I am posting this to rec.radio.amateur.homebrew and rec.radio.amateur.antenna

TIA,

Joe

"Wind" ?

As a rule of thumb, a thin wire has an inductance about 1 nH/mm, so a
straight wire about 18 mm long would have the required inductance. For
a thicker wire, about 25-30 mm straight wire would be required. Even a
single turn would increase the inductance quickly, so you would have
to shorten the wire considerably.

If 18 nH surface mount inductors exists, why not use them ? At least
the inductance would be much predictable.

A one inch length of #18 AWG wire is about 18 nH at VHF and above, according to the ARRL Handbook, 2004 edition, page 10.10. The equation is:

L = .00508b[ln(2b/a)-.75] where

L is in uH
b is length in inches
a is wire radius in inches
and change the .75 to 1 for VHF and above

So, it kind of makes sense why they don't sell lead-mounted 18 nH inductors. People would complain that they only got one lead, and it's a short lead at that.

If I were trying it, I'd try a one-turn loop of about 1/4 diameter with leads just long enough to solder into the circuit. Maybe all you need is a kinky piece of wire and adjust the kink to tune.

Good luck,
John (KD5YI)

Yes it is a very small incandescent lamp, about 1.5-2mm wide....I was thinking about using a 0603 white LED, they are very bright. I just found some Tek lamps but I am not sure if they are the right size. T 3/4 what is the 3/4???

Hi Reg, What I am attempting is to measure the PEP output power of a homebrew solid state amplifier. The amp should provide about 20 db power gain. A TLI will assure me I have a 50 ohm match. That was given in the orginal post. What I was looking for was a fairly accurate wattmeter, assuming the load was around 50 ohms. I was wanting to put a voltage divider at the input to my ATU. I have several replies stating the voltage divider must be frequency compensated to have a chance of accuracy. I have a surplus 100:1 scope probe I will take a look, and report back.

Could be worth trying. I experimented (unsuccessfully) with a red LED.

You may also be able to just order a replacement encoder assembly from
Deane Kidd (dektyr@teleport.com). He will need a part # from the
service manual before he can help.

Also, you could try Tom Neumann at www.tektrotom.de . Might be more
convenient if you're closer to the EU than the US.

Since everyone is being a little picky, there is also no such thing as
RMS power. When you use RMS voltage you get average power. :>)

Thanks Paul,

What do you mean by a thin wire? #20 magnet wire, #26?

Sounds like I can make my own and very easily, with just a 18mm length of
(not sure what size) wire.

Hi John,

Thanks for the info. Much more specific. I didn't realize I could make one from #18. I have the latest ARRL handbook, but maybe wasn't looking in the right place to see that info.

I don't have an inductance meter, so I am not sure how I would tune it. It is for 433.92MHz.

http://www.radiotronix.com/downloads/433_pair.pdf

The document is at the above address.

Thank you again,
Joe

Source record: 22994

Hmm, I actually thought the power output was 1/2 of what
I had calculated, so I'm a little confused.

I measured the 24v p-p using an oscilloscope (one of
those new fangled ones that actually let you set cursor
lines on the screen to bracket the waveform and it then
shows the voltage measurement on the screen, in this case
24v pp). I used an 8 ohm non-inductive 50w resistor
as a load (actually two of them, one per channel).

Now if I take 24 volts and reduce it by .707 I get 16.96,
and if I square that 287.9, and divide that by 8
(e**2)/r the result is 36. OK, I'm still missing
something. Maybe .707 * 12v (why HALF the pp voltage?),
yeah that gives just about 9 watts out.

BTW, I expected by the size of the power transformer I used,
and how hot the heat sinks get, that it wasn't giving more
than 10w per channel. And for driving a set of compact
speakers to just play music from my computer, that's
good enough.

Hi, Joe -

You won't tune it with an inductance meter. You could try constructing one of those RF millivoltmeters in the ARRL manual and reading the voltage across a (leadless) 50 Ohm output resistor. Then try kinking your wire (inductor) to see if you can tune it that way.

I strongly recommend you get a copy of "The ARRL UHF/Microwave Experimenter's Manual" and read it like there is no tomorrow. It will open your eyes about things that happen to wires at 434 MHz. For example, if you've made a few calculations, you may have discovered that an 18 nH inductor has a reactance of almost 50 Ohms at 434 MHz. That's why you are told to have no leads on components at that frequency. Have you seen a 440 MHz power amplifier? You will notice the absence of many inductors and capacitors compared to lower frequency amplifiers. That's because they use a few inches of PCB material to make inductors, capacitors, transmission lines.

If they did make leaded 18 nH inductors, how long would the leads be? If you purchase an 18 nH SMD inductor and put two 1/4 inch long #22 AWG wires on it, you will then have a 27 nH inductor. That doesn't solve your problem.

Your problem at 434 MHz will be that every component (with leads) that you add, you will also add several nH of inductance if your leads are longer than .1 inches or so.

If you analyze the receiving network, you will see that, if the antenna is 50 Ohms, the receiver sees 50 Ohms. So the network appears to simply be a filter. I would loose the receiver PI network, for sure. I think the transmitter is similar.

If it were me, I would forget both PI networks and even forget the pad on the transmitter. Put a cotton pickin' 6.8 inch antenna on the module and try it. Arrange your module so the antenna can be attached directly to the pin of the module, if possible.

Or, do these transmitters require the PI network to stay within FCC limits?

Anyway, good luck.

John

Hi Ken,

It is fine to measure peak to peak voltage but you can only use peak voltage to find power. Looking at a scope it is easier to find peak to peak than it is to find just peak as there is no line or mark where zero voltage is. Once you find peak to peak then just divide by 2 and you have peak.

Consider that your positive peak goes from zero to 12 volts and back to zero. The negative peak goes from zero to - 12 volts and back to zero. Although there is 24 volts peak to peak they do not happen at the same time. One is half a cycle later than the other. So you can only use one at a time. When the positive peak is at +12 volts there is no negative peak at that time. No power there.

Remember that the horizontal movement of the trace on the scope represents time. Draw a vertical line down the screen from a positive peak and you will see that there is nothing on the negative side at that time. Do the same with a negative peak. Draw a vertical line up and you will see that there is nothing on the positive side at that time.

At any given time all you have to work with is either a positive or a negative voltage. Not both at once.
You can use either the positive peak or the negative peak voltage (1/2 of peak to peak).

By the way, if the amplifier is not perfectly linear the positive and negative peaks may not be exactly the same. You could have some clipping on the positive peaks and not the negative peaks as an example.
Then you don't have a perfect sine wave and you will get an error trying to find rms voltage too as the .707 only works for a pure sine wave.

You first take 1/2 of peak to peak to find peak voltage. Then multiply the peak voltage by .707 to find rms voltage. Then square the rms voltage and divide that by the resistance. That gives power. 9 watts in your case.

Thru hole inductors were traditionally calibrated so that the inductance met
spec with 1/2 inch total length including leads, and not over a ground
plane. The smallest value of thru hole inductor I have ever seen is
27 nH. The true inductance (without the leads) of this inductor is
probably around 18 nH or less. Also, the inductance of thru hole
inductors typically drops about 5% over a ground plane.

You're probably better off winding your own air core inductor
and tweak it until your circuit is tuned where you want it.

Hi John,

In the old days, this question use to appear on the FCC's serious
tests - also required math too.

You already demonstrated as much with:
>If you analyze the receiving network, you will see that, if the antenna is
>50 Ohms, the receiver sees 50 Ohms. So the network appears to simply be a
>filter.
that meets the minimum technical requirment for coupling. All that
remains is the technical in-band/out-band issues (which segue into the
legal issues).

I don't understand what you're driving at here, Richard. I'm saying that an analysis of the PI network shows that it serves no "matching" purpose if the antenna is 50 Ohms and the receiver wants to see 50 Ohms. Its only purpose seems to be to provide a narrow bandwidth. Does the receiver need it? Probably not, unless there are a other transmitters in near by operating on an adjacent frequency.

As for the transmitter, perhaps it needs a filter, perhaps not. But, is a PI sufficient to meet any regulations if it does require a filter? Does the transmitter not meet the regulations without it? I remember hearing that these transmitters use SAW devices. Aren't SAW devices filters? All I'm saying is that, if you can meet the FCC rules without the PI filter, you don't need the filter at all.

Has anybody checked the inductance of a zero Ohm resistor (versus lead
length)?

Hi John

SAW, surface acoustic wave, filters are not transmitter pass filters.

As for the need, that is simple: OF COURSE it needs filtering. Simply observing the manufacturer's requirements reveals that:
>In most cases, the output of the transmitter may need a low-pass LC filter to reduce harmonic emissions.
As for matching:
>The output of the oscillator is derived directly from the collector of the oscillator transistor. It is, therefore, very sensitive to VSWR.
This, alone, demands filtering to reduce harmonics.

As for SAW filters. It has one, and uses it in the conventional manner (not as an output filter) for frequency determination in the oscillator.

Since the inductor is only a two "pin" component and assume you have
two PCB tracks at a suitable distance from each other, soldering
should not be a problem even without SMD experience. Using a toothpick
or some other device to keep the component steady, first solder one
end, let it cool for awhile and then solder the other end.

By the way, what type of capacitor are you using for that 8 pF ? If it
is a leaded component, it might have quite a few nH of wire
inductance. In addition to the SMD inductor, I would also recommend a
SMD capacitor, since these have a lower self inductance. Soldering it
close to the inductor should not be any harder.

I suggest that you buy some cheap SMD resistors or capacitors with the
same size package as the inductor or capacitor you are going to use
and solder these to a Vero 0.1" strip board to get some confidence in
SMD soldering, before installing the real components into the module.

For anyone interested in what an 18 nano-H inductor looks like under a magnifying glass -

3 turns of 0.33 mm diameter wire, wound on a 2.2 mm diameter former, over a length of 2.0 mm.

Its self-resonant frequency is 4.6 GHz and it is tuned to 1 GHz with a capacitor of 1.3 pF. Q = 330 at 1 GHz.

Joe, you're up against physics. 18nH is what you get moving a current
through just a couple of cm of straight wire. Before SMD, a microwave board
looked rather "fuzzy", with little tweaks of wire and snips of stripline. If
you want that 18 nH from one hole in a PCB to another one 01." away, then
you will have to bend that wire into a half loop. That ads inductance, so
the wire will have to be shortened some more.

SMD allows you to slap a lumped value into an exact location, without having
leads to worry about. The down side is that SMD is difficult to work with.
As usual, you have three choices: small, easy and workable. Pick any two.

Reg,
A 1/2 turn loop of the proper dimensions might be more practical. I recall
using one that was about .5 in high between .5 centers, made of #14 wire.
(it carried 10 amps). Don't remember the exact value, but it was probably a
little more than what he is looking for.

At any rate, as you say, it is important to add the inductance of the
circuit board traces to the inductor value. BTW, the last job I was on used
402 SM inductors down to about 10 nH, but that was at 2+ GHz.

Cleaning out some gear that hasn't been used enough to justify the space
it's taking up:

http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=3843642628

This package is helpful for general VHF/UHF testing and filter alignment
(and antenna work, if you have a directional coupler and RF probe or
power meter.) Also makes a decent tracking-generator substitute if you
have a spectrum analyzer with a max-hold feature.

Thanks! -- jm

Look for class E. Class D describes an amplifier that switches faster than the signal and has the output filtered to pass DC. Class E describes an amplifier that switches _at_ the signal rate and has a filter that has finite impedance at the fundamental and infinite impedance at all the odd harmonics. The result is that the output transistor drives a square-wave voltage and sees a sinusoidal current, so all the power goes to the output with none wasted.

There have been articles in QEX and even QST -- they even explain what I just said in sufficient detail to understand it.

Half pp because that gives you "peak power" which is a defined term
and not up for redefinition. Your P-P RMS power out into 8 ohms is
about 18W (but I've no calculator handy and my mental arithmetic these
days is very, very rusty.

Why not? p-p power is essentially "peak envelope power" isn't it? Are
you saying there's one rule for RF and another for audio??

Misleading answers.

If you _really_ want to get the actual average power delivered to the load you need to measure the voltage and current, multiply them and average (or multiply them, average and measure...). Using voltages assumes that your load is resistive. Using Vrms = 0.707 * Vpeak assumes sine waves, etc.

> you saying there's one rule for RF and another for audio??

A: There is such a thing as peak-to-peak power, it's just not generally very useful -- an example would be a 10Vrms sinewave drive to a 10 ohm capacitor. The instantaneous power going into the capacitor would peak at 5W and the instantaneous power going out of the capacitor would peak at 5W. If you defined delivered power as positive and returned power as negative then the peak-to-peak power would be 10W -- but you would almost never care.

B: P-P audio power is _not_ the same thing as "peak envelope power", at least not as defined in the US. Peak envelope power is average power of the RF at the peak of the envelope -- so if you are running sine-wave modulated AM with a PEP of 1500 watts into 50 ohms the peak _envelope_ power happens at an _rms_ RF voltage of 274V -- but the _peak_ power happens at the RF voltage peak of 387V, or 3kW.

>you saying there's one rule for RF and another for audio??

The definition of peak envelope power (PEP) is: "The average power
contained in one RF cycle at the crest of the modulation envelope".
(note that the definition says "AVERAGE power" not RMS power) This is
from the FCC definition.

If your SSB transmitter puts out 1500 watts pep with voice it also
will put out 1500 watts with full carrier inserted and no modulation.
(assuming power supplies do not sag)

Same maximum rf power with the carrier only difference is that with
the carrier all the rf cycles are at full power all the time. With
voice the rf reaches the same power levels but it is turned on and off
by the voice. The power levels also vary with the amplitude of the
voice. At full modulation the power levels of the rf cycles reach the
same levels as they do with the carrier. They just don't stay there as
long.

Thus from the definition "average power contained in one rf cycle at
the crest of the modulation envelope". It tells you that the average
rf power is measured at the maximum part of the modulation peak or in
other words the maximum average power that the transmitter reaches on
voice peaks. (if only one rf cycle reaches that power level that
qualifies)

This is one reason why I say that it is important to realize that
there is no such thing as rms power. If you read the FCC definition of
pep it does not say rms power, it says average power. Lots of people
refer to power as rms power.
Lots of people get confused over this thinking pep is something else.

PEP is the average power of one RF cycle at maximum modulation.

It is defined as pX in ITU-R radio regulations (RR 151).

The definition used by OFCOM, the UK licensing authority, contains the same words: "The average power ... in one RF cycle at the crest of the modulation envelope" - but it also contains two useful loopholes.

The full wording is: "The average power supplied to the antenna by a transmitter during one RF cycle at the crest of the modulation envelope taken under normal operating conditions."

That means UK amateurs are explicitly permitted to allow for feedline loss (very handy at UHF and higher) and abnormal transients aren't counted. Given our 400W PEP output limit, we need all the concessions we can get.

Hello,

due to the lack of space I have to blow out some NOS Siemens
electrolytics.

Datecoded 1984 NOS NIB they will surely be fully useful.

They have 470 uF at 250 V, two in series will provide stable and
reliable 240uF at 500 V.

Regular price for the box of 100 pcs is EUR 80,-

Special offer for the box of 100 pcs: EUR 50,-

Thatï¿½s 50ct for a 5$ electrolytic !!!!

If you buy 10 or more boxes price will be EUR 42,- per box.

See

http://www.askjanfirst.com/kb/KON8311.jpg for a picture and

http://www.askjanfirst.com

for our homepage.

or send me an email if you need more info.

I ship worldwide, shipping upon request.

Okay, gentlemen, I can see where you're coming from now.
Incidentally, the (UK) definition above could be construed to allow
for some really serious QRO if one takes "normal operating conditions"
to refer to *atmospheric* conditions rather than those of the station
set-up. When's the next sunspot minima? :-}

==========

It's also very handy on 160 meters.

For example, if the antenna is just a 15-feet length of wire and 400 watts PEP are fed into it over 115 feet of 600-ohm single-wire transmission line, who needs concessions?

A 15-feet length of wire, all by itself, is quite efficient on 160 meters. Nearly all of the 400 watts fed into it will be radiated and the licensing regulations are not violated.

Furthermore, because a transmission line of that particular length accurately does the impedance matching, a tuner becomes redundent.

Reg.

Thanks for the information and article links.

I have some articles fromm Sokal and Raab on E. Also familiar with Steve
Coultier's class-E web site.

I have a QEX/QST compilation CD somewhere.

Do you have any month/year references to hand?

Tnx

Hang on a minute, Ian!
I've just looked in your book and in section 6-5 you say in a passage
on Peak Envelope Power: "PEP is the RMS RF power level at the peak of
the modulating waveform." "RMS"? Which is it: RMS or AVERAGE??
Not getting confused, are you? ;-}

Message-ID: <%US7d.1593$M05.938@newsread3.news.pas.earthlink.net>
Source record: 22932

I hope some of you will remember but I built the EB63 kit and substituted MRF455's for the MRF454's. I was told by an RF Engineer thet 2SC2290's are often substituted and should work fine. I have them now but have a few questions. I looked at a schematic for a Texas Star DX250 because it uses 2SC2290's. I noticed that the transformers both have 3:1 ratios instead of the 4:1 in the EB63. Should I go ahead and change both of mine to 3:1? Can anyone think of anything else that should be considered here.

Thanks,
Chris

Hi everyone,

Below you will find my attempt to show in text-form, a circuit
fragment from a 145Mhz amplifier:

```
--------------capacitor-------------------------------transistor base
|
|
I
|
coil
|
|
|
|
-------------------------------------------------------------GND
```

The cap's value is 1nF; the inductor's is 0.4uH.
The cap (I assume) is to couple one amplifier stage into the next
(50ohm source/load) with minimal attenuation of the desired VHF
signal. But like what's the purpose of this inductor to ground??

It's there to bias the transistor.

In this case, the base of the transistor (I'm assuming bipolar so I
say base) is at DC ground. But if you just shorted the base to ground,
the signal could not get into the transistor. So you put that RF choke there,
so the base sees ground at DC, but the signal sees a relatively high
impedance.

The inductor keeps the transistor base at DC ground potential (probably the same potential as the not-shown emitter). This makes the transistor only conduct on positive half-cycles of the drive signal, which is a very non-linear condition that generates lot's of harmonic content. It's also common to put a little resistance in series with the inductor, which slightly reverse-biases the transistor because the RF waveform can then swing more toward the negative than the positive. A little reverse bias causes the transistor to conduct over a smaller portion of the input cycle, which enhances higher-order harmonic generation.

With a 1nf coupling cap, there's no impedance matching happening because the capacitive reactance is so low that the impedances on both sides of the cap are essentially connected together.

The inductor provides a bias path to ground, to hold the average
transistor base voltage at zero volts, while passing the base
current. It also forms a resonant circuit with the capacitor (and
base capacitance) that has a peak response at some frequency,
hopefully in the middle of the band being amplified. This resonance
lowers the impedance at the input side of the capacitor and raises it
at the base node, stepping the input voltage up and the input current
down.

Right. I didn't pay any attention to the given values. They produce
a resonance around 8 megahertz.

================================

But to keep things in proportion -

To radiate 400 watts from a 15-feet antenna wire, fed via a 115-feet,
600-ohm, single-wire, overhead transmission line, would require a
transmitter power of the order of 1.4 Megawatts.

So before ordering the materials to construct such an antenna and feedline
it would be better to forget all about it!

<sorry> <smiley>

>Sources, please.

Rms voltage and current are also called "the effective values".

If you have heard that average power is 1/2 of peak power we could
investigate why.

The rms voltage and rms current of a sine wave are found by
multiplying peak voltage by .707. Same for current.
If you multiply .707 by .707 that gives you .5 or 1/2.

1 volt peak Ac voltage times 1 volt peak / 1 ohm = 1 watt peak power.

1 volt peak times .707 = .707 rms volts. .707 rms volts times .707 rms
volts = .5 / 1 ohm = .5 watts average power.

"It takes twice the Ac peak power to provide the same amount of heat
as it does average DC power." Therefore 1/2 the peak Ac power is equal
to it's average power.

Note that rms voltage is defined as the amount of Ac voltage that will
cause the same amount of heating in a resistor as an amount of DC
voltage.

Also note that when describing rms voltage and its heating effects,
that it does not say amount of power required to do the same amount of
heating. It says the amount of rms voltage to do the same amount of
heating in a resistor. (thus, effective voltage) This is where many

get confused.

If you want to know the amount of power you must square the voltage
and divide by the resistance.
There is that .707 x .707 = .5 again for Ac power. (E squared /R)

2000 ARRL handbook 6.6 chapter 6, RMS VOLTAGES AND CURRENTS.

At 145 MHz, the reactance of the cap is:

$$Xc = \frac{1}{2\pi fC}$$

$$= \frac{1}{6.28 * 1.45E8\ Hz * 1.0E-9\ F} \sim 1.1\ ohms$$

So it's likely not effecting a match to 50 ohms.

The reactance of the inductor is:

$$Xl = 2\pi fL$$

$$= 6.28 * 1.45E8\ Hz * 4.0E-7\ H \sim 364\ ohms$$

so they're not resonant at 145MHz.

Since the resonant frequency of the LC is:

```
1
f = --------------
2pi(sqrt LC)
```

it's tuned to

```
1
f = ----------------------------- ~ 7.96MHz
6.28 * sqrt (4E-7H * 1E-9F)
```

which is nowhere near 145MHz.

If that's all there is to the circuit, my guess is that it's a highpass filter with the coil doing double duty as a DC return for the base as well as a fairly high reactance load for the driver. Also, (WAG) since the transistor's input resistance and capacitance will appear effectively in parallel with the coil, it may wind up looking like something closer to 50 ohms than 364 ohms to the driver.

The input impedance of the transistor is capacitive. So the inductor very likely resonates with it at the working frequency.

You might be on to something here, Reg. Maybe the inductor's there to
'neutralise' the transistor's input capacitance.
The parallel tuned circuit formed by the inductor and the transistor
input capacitance would have a maximum impedance at 145Mhz if the
transistor's (capacitive) input impedance were about 3pF., which
doesn't sound far out for an RF small-signal tranny. Without that
inductor, sure there'd be no bias on the base, but additionally, the
input capacitance of the transistor will shunt away much of the VHF
input signal to ground.
Does that make sense?

A capacitor has a very low impedance to high-frequency (i.e., 145MHz)
signals and a very high impedance to low-frequency (i.e., DC) signals.

An inductor is the other way around - very low impedance to low
frequency (DC) signals and very high impedance to high frequency (2m).

The inductor allows DC bias currents to flow while not shunting the
desired 2m RF to ground.

The capacitor passes the 2m drive signal from the previous stage without
attenuation, while keeping the DC from the previous stage out of this one.

2867. Reg's programs and Windows-XP

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-10-03 23:41:44 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <cjq2nodv1@sparta.btinternet.com>
Source record: 22799

If your computer's operating system is Windows-XP some of you may have a
problem with running my programs full-screen. If so -

Right click on the program's Icon.
Click Properties.
Click Screen.
Click Full Screen.
Click Apply.
Click OK.

and all should be fine.

If you have a lot of programs in a common folder there appears to be no way
of changing all of them to full-screen simultaneously. You will have to do
it one by one. (Unless somebody can discover an easier way.)

I have two machines, Windows-98 and Windows-XP. If a problem should arise
with any other Windows versions please let me know.

....

==========

I've never heard of Win2K Pro.

I understand DOS emulator programs are very good - if you can find a DOS
emulator program which will run under Win2K Pro.

Just don't throw away your old computers.

Reg.

>You missed my question. Who defines these terms? I know that RMS,
>average and effective are often used interchangeably, but who or what
>organization says there is "no such thing as RMS power", and why?

No I didn't miss your question. I thought I gave you enough
information so that you could figure out the "why" yourself.

I don't know of any organization that says "there is no such thing as
rms power". What would be the point. That would be like formally
declaring "water doesn't run uphill", since there is no proof or
evidence that water runs uphill.

I also don't know of any organization that says there is such a thing
as rms power although you will often find it referred to in many
articles and advertisements. Even some of the older ARRL handbooks may
call it rms power but I don't think you will find that in the newer
versions.

Most any AC circuit theory will explain how values of a sine waves are
found and the relation of those values. The reference I quoted from
the ARRL handbook does very nicely at explaining it. It is worth a few
minutes to read. Only a couple of paragraphs will get you there. (you
will see the absence of rms power mentioned)

The thing to consider is that once you multiply an rms value by
another rms value the result is no longer an rms value.
If it were then you could use any of the rms factors to convert it to
peak etc.

Consider 1 volt peak x .707 = .707 volts rms. .707 volts x .707 volts
= .5. Divide that by 1 ohm and you have 1/2 watt.

Using rms factors, convert the rms values to peak. .707 volts x 1.414
= 1 volt peak. OK.

Now try and find peak power like you would find peak voltage from a known rms value.
Do that with the power value that you want to call rms power and you have .5 x 1.414 = .707 watts. Not the 1 watt peak you were looking for.

;-) You just aren't working with small enough, high enough frequency
circuits, Reg.

3 turns of 28AWG on a 4-40 (USA) screw (remove the screw, of course)
will give you about 18 nH. Unloaded Q at 440MHz will be around 200.

Easy enough to use SMT components soldered to a piece of copper-clad
for a ground plane. Just put down the two caps and the shunt resistor
"tombstone" style, one end soldered to the ground plane and the other
up in the air, separated by enough distance to put the series coil and
resistor between them. You can keep the parasitic L and C very low
indeed this way. You can also use tiny squares of copper-clad glued
down to the ground plane as tie points.

It's also possible to mechanically make a simple circuit like this on
copper-clad using surface mount parts, by scribing lines with
something like an X-Acto knife and removing strips of copper. In this
case, I could see scribing four lines across the board, separated by
about 1/16 inch, and removing two copper strips, one from between the
first and second scribe, and one from between the thrid and fourth
scribe. That leaves a trace about 1/16 inch wide. Cut gaps in the
trace, about 1/16 inch long, where you want to solder down series
components. Solder shunt components across from the trace to the
copper ground plane. Bridge across the trace with a copper strap to
connect the two gound plane sides, with the bridge up in the air over
the trace. Nice to have a ground plane on the opposite side, with
some holes and wires to connect to the top-side ground planes, but not
necessary. I'm thinking 0805 parts with the sizes I mentioned...make
things slightly larger for 1206. You can make the trace be a 50 ohm
transmission line if you want, by sizing things right.

Cheers,
Tom

Yadda, yadda, yadda

The term "RMS POWER" while not technically correct for anything practical is tossed about and I suspect it is 'meant' to mean true or average power as generally understood by those schooled in the field. One of the reasons for formal training (or understanding of that training) is so we have terminology which we have in common. One word or phrase relates to the same concept for everyone in the discussion.

"Peak-to-peak power" is quite meaningless. P-P voltage and current can be measured, but power is a second order quantity requiring voltage and current and an in-phase component as well...and multiplication of these quantities (that's what makes it second order). This takes care of the phase relationships and when the voltage goes negative, the current does (the in-phase component does) and two negatives make a positive and you again have positive power. There is NO amount of voltage or current which occurs which is the P-P value. This is only in the eye of the beholder who chooses to relate two parts of a waveform which occur at different times.

Question:

In a pulsed situation like a common bridge rectifier, capacitor input filter DC supply, can the true power be determined by measuring the Irms and Vrms (on the AC side) and doing P = Irms X Vrms ???

Anybody sure enough to say???

2880. Frequency stability in vacuum tube VFOs, how do you do it?

Newsgroup: rec.radio.amateur.homebrew

From: Robert Casey <wa2ise@ix.netcom.com>
Message-ID: <4161FA9D.6070100@ix.netcom.com>
Source record: 22812

The local oscillator in "All American 5ive" vacuum tube AM radios all drift an annoying amount at the upper end of the AM BC MW band. The oscillator would be running at about 2MHz, and warm up drift (from cold start to about an hour being on) is typically 20KHz. Enough to make that station at 1520 tune itself out. AM radios used a hartley style oscillator using the equivalent of a triode with its plate to B+, grid capacitivitly coupled to the LC osc tank, and cathode connected to a secondary winding on the LC osc tank. Usually an air variable cap, and fixed inductor wound on a cardboard coil form.

VFO's for ham radio work would involve higher frequencies, and I would think that they not drift anywhere as bad as the AM radios did. I looked at a few tube VFO schematics, and I don't see anything that different from the AM radio hartley osc circuit. So how did they avoid drift, or were you expected to leave your VFO on all the time?

Slightly beter components, time to use and change some capacitors to
compensante for the drift, and some stayed on all the time. Voltage
regulation was usually used also.

Voltage regulator tubes, matching components for thermal drift, solid (physical) construction, for starts. Shielding not only for noise, but also to minimize thermal drift. If you didn't leave the whole thing on all the time, maybe you left the filaments on. If you actually turned the thing off, be ready to wait an hour or so after power up for things to settle down.

Collins used different techniques -- a permeability tuned oscillator among them.

Growing up, a bunch of us were hams, living in a few block radius. One character was really proud of the VFO he'd built; very solid construction, quality parts, the whole 9 yards.

He had it sitting on a shelf that was mounted to an outside wall of his house. We'd go pound on the outside of the wall, and you could hear the thing wobble like mad.

Source record: 22815

Mostly better design and charericterization. The VFO's designs
were tested for temperature drift, and temperature-compensating
capacitors were made part of the design. I think a few radio VFO's
were actually tweaked as part of the unit test for temperature stability,
but not sure. It would have been expensive.

The capacitors are coded:

N - for negative temperature coefficient
P - for positive temperature coefficient
NP0 - for no temperature coefficient.

So for example, N750 would have -750 ppm of capacitance change
per degree C.

The other challenge was good inductor design, since they can be
temperature dependent as well.

>average power as generally understood by those schooled in the field.

It was somewhat in that sense that I was trying to use the term about 15 years ago. But I was shot down for a number of reasons... with all of which, I now agree.

1. When used without any qualifier, "power" always means the value averaged over one or more complete cycles, so it is redundant and confusing to add "RMS" where in fact no qualifier is necessary. This is the strongest technical reason for not using it.

2. I was using "RMS power" to mean exactly what Steve says: "average power as generally understood by those schooled in the field", or "power averaged by the correct use of the RMS method". However, that attempt to condense a much bigger concept into two words just does not work.

It's even worse than a simple failure to communicate. The mere mention of "RMS power" is guaranteed to hijack the whole discussion, and the point you actually wanted to make will be lost forever.

3. Any term that is used in the "hi-fi" industry - even by the so-called "good guys" - is automatically tainted.

In the end, I decided that using "RMS power" was causing *many* more bad effects than good... and after 15 years, I'm still being punished for it :-)

Those are the reasons why I now come down firmly on the side of "just call it power".

> bugs in it. Can you help? ;-)

Hi Paul,
connect to Micro$oft Update and dowload all patches, service packs and
improvements the server will find for you. This may remove about
25,000 your bugs. You will get some 48,000 brand new bugs instead and
for free !! ;-)

But, Paul, don't worry. Remember the programmer's axioma:
1/ Every computer program contains at least one bug.
2/ Removing of one bug from a program merges at least two other bugs
into the program.
3/ So-called debugging is a process of making a chain of bugs, which
performs the operations originally required.

Thanks to the axiom 3, your Win2k Pro probably performs all functions
as needed. Only a few people know that the process is performed by
long chains of bugs ...

Not satisfied yet ? So AVOID APPROACHING TO COMPUTERS FOR THE REST OF
YOUR LIFE ! :-}

BR from Ivan OK1SIP

P.S.: TNX to Reg for his superb collection of programs.

2887. OT: Monitor woes

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-10-05 11:52:14 UTC
From: mike@corn2.freeserve.co.uk
Message-ID: <416286c0.178933668@news.freeserve.net>

Hi Folks,
I guess this is OT but I really don't know where else to ask for the info.

I have, no, had a very useful svga monitor with a 9" screen sitting on my shack bench for various AR related uses until it started playing silly bu**ers recently.

When it is initially turned on, the display is clean and sharp but after about 30 mins or so the display starts dimming and going out of focus. There are no nasty noises or smells coming from it and AFIK there has been no smoke released.

Is this a terminal case or not?

If not, what should I be looking for? an R going High, a C leaking or whatever. Any help appreciated, I have no TV/monitor service experience but I'm used to HV circuits and Homebrewing. I have a 20Mhz dual trace scope, DMM and Analog VM (20k ohm V) available for test equipment.

I suppose I should tell what model it is just in case its a stock fault. Its a Smile 9" Svga monitor, Part Number CB0913DL. There is also the number KFC CB0913DL on the manufactures label. Could this be from a Kentucky Fried Chicken, Point of Sale Till ?

Thanks for your time reading this and I hope its not too OT.

>you expected to leave your VFO on all the time?
>
Several ways:

1) Better components - Drift of the kind being discussed is mostly due to thermal effects. Capacitors, inductors and even resistors change value when heated, and the component selection makes a *big* difference in stability. For example, a variable capacitor with aluminum plates is inherently more affected by temperature than one of similar construction with brass plates.

2) Better design - Reducing heat reduces thermal drift. High C is usually less drifty than low C. A high gain tube that is loosely coupled to the tank circuit is usually more stable than a low gain tube tightly coupled to the tank circuit. There's lots more, of course.

3) "Weakest link" - As sources of drift are corrected, sources which were once negligible become dominant. Often a design will go through several revisions as sources of drift are identified and corrected.

4) Compensation - When all else is done, the use of thermal compensating caps can reduce drift to very low levels.

Remember too that "stable" is user-defined. A rig that drifts 300 Hz on each transmission might be considered "very stable" on AM or FM, barely acceptable on CW, and useless on SSB or FSK/PSK

...snippage>>>

I tested an RCA AA5 I have here (uses battery tubes) and
a modified Hallicrafters S120 (also basically AA5) and neither drifted
very far on turn on. The worst was the RCA! at 1.8khz in the first 5
minutes. The RCA drifted 3khz in the first 5 minutes from cold start.
However once both had a chance to fully warm up (20minutes)
the drift was in the less than 100hz region. Generally most AA5
radios for AM broadcast reperesent the lowest possible cost designs
with the least consideration for circuit performance above a minimal
level.

Tubes experence fairly large initial warm up temperature changes
and the surrounding circuits often do as a result of that. When you
consider that your going from 20c to greater than 50C in the first few
minutes there is no surprize there (transistor VFOs would be hard
pressed for that great a temperature change too!).

The solution is manifold. use components that experience minimal
dimensional or other characteristic change for temperature. Coils
and capacitors are the biggest influence here.

The AA5 you have uses a hartly osc and the common circuit has less
than 4 components in the VFO, namely the tube, variable capactor,
a padder cap (vfixed usually) and the coil (slug tuned). Lets look at
each. In the design the tube has changes at warm up of both
mechanical, things move such as cathode to grid spacing when heated
and electrical its operating point shifts as the tube reaches operting
temperture. The mechanical tuning cap, while likely the most stable
device if heated enough the aluminum plates will deform and posible
change spacing, there may be other forces from the chassis mounting
as that warms too. The padder cap is usually a cheap component
in AA5s and the typical part used has a poor temperature coefficienct.
Lastly the coil, this can also be a big factor as the coiled wire can
mechanically change dimension from heating but, you also have a
powered iron or ferrite tuning slug that also has a temperature
coefficient and the cheaper (older) materials can really be poor
with temperature. I might add that some of the AA5s coils were wax
impregnated and the materials used can also experience dimensional

changes while heating up causing the coild to deform. I may add
that operating voltage changes can influence stability and drift.
Tubes are no worse than transistors, just warmer. What differes is
that there are two sources of voltage sensitive drift in tubes, The
heater(filament) voltage must be stable as it affects tube operating
characteristices such as gain and also the environment due to heating
of the area around the tube. The other votage that must be stable is
the B+ (high votage usually but can be anywhere from 12 to 300v
depending on tube and circuit).

Hopefully you can see that VFO design superficially can be very simple
but has many details that can influence stability. It is possible to
design a tube (or transistor) VFO that is very stable but it requires
good components, temperature compensation and good mechanical
construction.

If you want stability in your AA5... Better cooling most ventilated
very poorly. Other things, put the components away from the tube
[but not too far ;)] to minimize heating effects. Regulate the
voltages. The latter is harder as the average AA5 uses a series
heater string that has a sometime shakey warmup. Also the AA5
uses a poor supply in the form of a 35w4 half wave rectifier that has
to warm up to work (it's a tube too!) and the lack of good power
supply filtering (add to this the caps are old!!).

As a experiment with tubes:
The Hallicrafters was a basket case when I got it so modiflying it was
a reasonable thing to do (just to make it work) lest the purist
classic radio people protest. First was converting from live chassis
(typical AA5 off the mains) by adding a transformer to supply 120V for
rectifier and 6.3v for the heaters. Rewired the heaters for 6.3V and
change the 50C5 to a 6AQ5 I had on hand (rewire socket). This radio
used a selenium rectifier which was bad so silicon bridge rectifier
was used with new 100uf caps as filter to get clean 150v B+. Since
If selectivity was minimal I added an old 6KHZ mechanical filter and a
second IF amp tube (5899 subsub mini) to fix that and and a bit of
gain. Replace a dozen poor quality and just plain bad caps in various
points including the Local osc section (VFO). I also added a 6AR5
bfo/product detector for ssb operation as the original BFO design was
poor at best. It was a major rebuild with many circuit changes mostly
for fun. However the 6BE6 and the Hartly local osc (VFO) was
retained to keep the tuning dial something near calibrated. A stable
VFO using tubes was straghtforward using good quality parts (both the
BFO and the LO are LC osc). The result is a stable (after warm up)
general purpose reciever that I use for 3885KHz AM and occasional 75m
SSB listening.

Actually the drift is thermal not due to voltage variations. Voltage regulation is not an issue these days with the power line usually holding to better than one percent.

In order to halt the drift, you need to replace some of the tuning capacitance with negatifve temperature coefficient capacitors. How much you use will depend on how much the drift is for a given temperature variation. It drifts more at the high end because there is less capacitance involved, causing a small variation to make the frequency move farther.

You can start with a negative temperature coefficient capacitor of, say 10 pF across the tuning capacitor and see if you can still align the local oscillator. Mount the capacitor as close to the source of heat (the tube) as possible and see what happens.

I have compensated many oscillators for thermal drift. You can also see if perhaps the existing components are being heated by a power resistor and if possible increase the distance. There is a bit of art involved but it's all pretty basic.

The big problem, is where can you buy negative temperature coefficient capacitors? They used to be plentiful but I don't know about these days.

Your answer is what my point is all about. 2 is not an rms factor.
Nowhere do you use 2 to find an rms value. But 2 is used when
associated with average values.

As Steve said in another post, power is often referred to as rms power
as it is derived from rms voltage. But it is important to realize that
there is a difference even though it may not be stated.

If it were really rms power then you should be able to find peak power
by multiplying by 1.414 as you do with rms voltage. But that doesn't
work because power is not an rms value.

Hi,

At the high end of the AM band, the oscillator capacitor is
at its lowest capacitance (almost fully un-meshed). So, any
variations in circuit capacitance due to tube electrode
dimensions, capacitors with non-zero tempcos or similar
happenings in the oscillator coil will have a greater effect than
at the low frequency end.

For this reason, a stable LC-tunable VFO would not normally
be designed to tune the 3:1 ratio that an AM local oscillator is
expected to.

Cheers - Joe

People who use the term "rms power" are braggarts, attempting to show-off how psuedo scientifically and engineering-ly educated, politically-correct, and clever they are.

Whereas all they accomplish is to display to the mostly sensible world their abysmal ignorance.

Articles in Audio Hi-Fi magazines fall below even lower standards of silly journalism. There ought to be a law against it !

There's only one sort of "power" and that is simply "power". I have serious doubts about such vague and indeterminate notions as "reflected" power.

In all my experience I have never found any use for such terms.

There are lots of published designs for low noise
preamps for 2M. The Mitsubishi MGF1302 seems to
be the most popular device for homebrew VHF/UHF
preamps. I use the MGF1302 in my preamps for
2M, 70CM and 23CM.

Use your favourite search engine to search for:
low noise GaAsFET preamp for 2M

See YU1AW's excellent designs at:
http://www.qsl.net/yu1aw/engl.htm

See W5UN's MGF1302 preamp at:
http://web.wt.net/~w5un/preampbx.gif
It must be very good because he can sometimes
hear my puny 250W to a single 9 element Yagi
on EME.

> I would like it if the plans should also be able
> to handle 100 Watts from the tranceiver.

For high power on VHF, you should use good
quality co-ax relays and a sequencer.

The ARRL handbook has some good designs for
2M preamps and an RX/TX sequencer.

73, C U on 2M.

Some VFO's e.g. in the BC221 use a compensation
coil, moved by a bi-metal, inside the tuning coil as temperature
compensation.

While it's a misnomer, there's a reason the audio folks use the term "RMS
power".

Back when stereo was hi-fi, amplifiers were simply rated in watts output. The
test method was simple: you fed a sine-wave audio tone into the amp and
measured the continuous output power into a matched resistor load. A "50 watt"
amplifer could deliver 50 watts of audio power continuously.

Then a bunch of things happened.....

First off, there was stereo. Audio amplifiers became 2 channel, usually with a
common power supply. Manufacturers found they could get more power if only one
channel was operating - particularly if the power supply was skimpy to begin
with. So they tested that way, and doubled the result.

Then came solid state. Some early designs could deliver amazing levels of power
into very low impedance loads - for a short time, anyway. So the idea was born
to test the amps by feeding a pulsed signal rather than a continuous tone, and
using a very low impedance dummy load.Plus one channel at a time. Plus
measuring peak power, not average power. With big capacitors in the power
supply, and all the tricks optimized, some amazing power levels could be
measured.

Of course you'd never realize such power in actual operation, but the
manufacturers rationalized that music wasn't sine waves anyway.

End result was that an amp which would have been rated as maybe a "20 watt
stereo amplifier" under the old scheme (two 20 watt channels operating
simultaneously) could be rated as high as "200 watts IHF music power" or some
such. All sorts of terms were invented, mostly to favor a particular test
method.

The serious audio folks coined the term "rms power" to mean the old way of actually feeding a continous tone to all channels and measuring the continuous audio power developed.

Joe, back in the 'old days' everyone left his VFO energized on a
24-hours basis, to improve stability. Same with our receivers,
particularly when SSB became the vogue.

That is similar to how computer speakers can get 50 to 100 watts rating out
of a wall cube and a look inside will see the speakers rated around 2 watts.

Hello all,
Recently I purchased a low-power VHF transmitter kit from Ramsey. After building this kit, I have discovered that it will not work for my purpose. I am trying to transmit audio and video about 20 feet from a satellite receiver to my bedroom. The power output from the transmitter is so low that the picture quality is very poor. I am a novice and I am hoping the experts that use these newsgroups can help me. I will post a link to the Ramsey kit manual. Will some of you guys please take a look at this manual, and suggest some simple (hopefully) methods to increase the power of this transmitter? There is no chance of interference with the neighbors, as my nearest neighbor is far away. Any help would be greatly appreciated. If you want to email the response, please send it to mndflmr@hotmail.com

Here is the link to the kit manual:
http://www.ramseyelectronics.com/downloads/manuals/TV6.pdf

Thanks for any help

Joe

Hi Tom,

Being so new at this, I don't even know what you mean by 'tombstone style', and it sounds like an awful lot of work to be scoring pcboard with an Xacto knife to create transmission line effects.

I talked with a tech rep from radiotronix today. They called me because I ordered a half dozen modules from mouser. He explained that the pi circuit on the TX is so the TX sees 50 ohms, which is pretty critical. I have not done anything with the transmitter modules yet (they are from Velleman because they are thru hole), but I am building a receiver board on pc board using pcbexpress and single sided copper pcboard. It will be the first prototype. Now that I have it working on a breadboard I am going to build one and see how it works. I am planning on using a straight piece of (20ga) wire for the 18nH inductor and using the T network of 2 8pf caps beside it. The tech said this is just a low pass filter, but it seems to make a difference in receiver sensitivity. The noise on the receiver is supposed to be there according to him. It is between 1Khz and 1.5Khz. he said some people use the data slicer pin with a holtek ht12D decoder, which i am doing or you can also use a micro to look for the bit pattern and decode the signal. I am just using the TV (transmission valid) to set off the rest of my circuit which, right now, consists of a latch and an LED.

There's a place called You do it Electronics in Needham, which is about 10 miles west of Boston. It is not a surplus place tho. There's also jabbour electronics in Rhode Island, right over the state line just off Interstate 95. I think it is exit 24, not sure. Then there's Ocean State Electronics, which is mostly pcb stuff but they are in Rhode Island too, I am not sure if it's Warwick, but they are on the web, do a google for them.
Those are about the only ones I know about in this area.

hth,
Joe

The transmitter would necessarily comply with the FCC rules. Modifying it
to increase power is illegal.

If it does not transmit the distance represented, then either the
construction is wrong or the specifications are wrong.

At this distance can only attempt.....

1.Measure DC voltages at CRT base when OK, measure again when faulty - one of them will have changed. If you want to be fancy, check for AC ripple levels on HT and 12v lines -will be HF due switchmode power supply... With any luck, board will be marked. Warning - there is HT there, so be careful! Also, check for dry joints, percussive testing, temperature cycling with a hairdryer on hot/cold cycles.

2.A brute force method I use is - when it faults, see if adjusting the screen and focus voltages (on EHT transfomer, usually marked F and S). If this fixes it, then EHT transformer (or, more particularly, the diodes inside it) are faulty. Dont fancy your chances of getting a replacement..... and this IS a common monitor fault.

Among the numbers on the back will be a "FCC ID No ..xxxxxxxx" - go to the FCC website, it will tell you who made it - usually no relationship to the brand on the front!

Good luck, its a nice size to have in the shack because of its small footprint....

I used a 10pF ceramic temperature stability not marked
across the LC tank. Mounted it directly under the 12BE6
tube so it would be warmed by that tube, like a hen on
eggs. One lead connecting to a center ground peg of the
tube socket, and the other a wire jumper to the top of the
LO tank. Keeps the radio stable at 1520 from a cold start
to warm. Only thing is now the radio top ends at about
1540. Also reasonably stable at 1160, and 660.

Ten milliwatts is more than enough for a measly 20 feet, and i am
sure the kit puts out more than that.
Match (tune) the antennas at both ends for starters, orient them to
point at each other is the next step, and have a decent (sensitive)
receiver.
I only had a matched antenna at the (sensitive) receiver, and got
about 100 or so feet at 10mW.

You can easily build what you need using single-sided board: a continuous groundplane, components soldered on top, and connections made using sticky-backed copper tape (available at craft stores for stained-glass work).

If you cut strips 0.1in wide, these will be a good approximation to 50-ohm microstrip, for the relatively low frequencies and short lengths that you will need. On the reverse side, use broader the copper tape to link the groundplanes of your extension and the Radiotronix module.

Simply lay the SMD components against each other, and solder them together... but before you do, mark where the connections through to ground will need to be, for the two capacitors in the pi-network and possibly other places. Then drill the board and insert links of thick wire (14AWG) so that the ground connections will have zero length beyond the thickness of the board - but I really do mean ZERO, or else your network will not perform correctly. The ground links must be touching the ends of the capacitor chips before you solder them.

Likewise, use ZERO lead lengths inside the pi-network. Butt the ends of the two Cs and the L chips directly together, and solder. Any "connecting leads" must be restricted to the places that can use 50-ohm microstrip.

This construction method is very quick and simple. The SMD parts are well-enough anchored to the board for all normal conditions of use.

>I talked with a tech rep from radiotronix today. They called me
>because I ordered a half dozen modules from mouser. He explained that
>the pi circuit on the TX is so the TX sees 50 ohms, which is pretty
>critical.

- so remember what I just said about zero lead lengths.

>filter, but it seems to make a difference in receiver sensitivity.

On the face of it, this pi-network has a 1:1 impedance transformation (two equal capacitors) so it shouldn't make any difference. However, there may be stray capacitances and/or inductances in the module that we don't know about. Bottom line is, this network is what the Radiotromix techs have found to work.

Since you don't have the design experience and the test equipment to measure how the whole thing performs, you would be very wise to copy EXACTLY what Radiometrix did, which includes building the whole network using the best possible construction practice.

Also, a straight piece of wire is actually a short length of transmission line: it does not have quite the same electrical properties as an inductor. So use an 18nH chip inductor like Radiometrix said.

This is really part of your "contract" with the module manufacturer. It isn't fair or reasonable to expect their tech support to second-guess what the effects of every individual user's network might be, if they're all slightly different. You might get away with it this time, but some of the worst tech-support problems are caused by people who declare:

"I did exactly what you said..."

[Now follows 20 minutes of intensive cross-examination over the phone]

"... oh, apart from all these things that are different."

[Deleted: strange sounds on the phone line. The tech has the curly cord gripped in both hands. He's puling it out straight, and he has a red glint in his eyes. Be very thankful that you're several hundred miles away...]

Sorry, that wasn't quite clear (not enough coffee yet this morning).

The continuous groundplane is on the underside of the board. All the SMD components are on the bare fibreglass side. The SMD components are held in place by soldering them directly to each other, to the ground links, to the striplines, and to various other fixed points.

No board etching is required, and this technique will is good to frequencies well above 1GHz.

The 0.1in stripline width was for standard 0.064in FR-4. You can obviously refine that calculation if you want, but there's little point for this particular application.

Something is broken. Either at the transmitter or receiver. A
mis-matched antenna couldn't possibly account for a poor quality
picture at 20 feet. I presume this transmitter is designed to transmit
a signal via antenna to source and not over transmission line. Here
are some probable causes:

1) The transmitter output stage is broken.
2) The receiver is not working (see how well it picks up other
stations).
3) The antenna at either end is disconnected.
4) There is Radio-frequency interference (RFI) such as from a
computer.

Tombstone style...just solder one end to the copper-clad board, and
the other end sticking up in the air. Looks like a micro-size
tombstone sticking up from the board.

...

It's really not all that difficult. Just use a ruler to guide the
knife, use a sharp knife, and the strips you want to remove can
usually just be pulled up in one piece (each). Or do it as Ian
suggested, with sticky copper tape.

As Ian wrote, keep lead lengths extremely short, like "zero." He
suggested putting a piece of heavy copper wire through the board where
you want to connect to the ground plane. Another way is to simply
drill a hole through the board and drop an 0805-size surface mount
part into the hole, and solder both ends. A 1/16" hole would work,
but you'd do better to pick a size that just fits the part you want to
use. Not all 0805 parts are quite the same size, but the body lengths
are pretty accurate and work nicely in 1/16" thick board material.
Any of the methods mentioned by Ian and myself will work well, and all
are reasonably easy to implement with a bit of practice and patience.

Cheers,
Tom

One method of "etching" that worked for me was using a reamer
bit on a drill press to cut through the copper and barely into
the PCB material. This has the advantage of leaving a ground
plane in between the active traces. Also great for scouring
and sizing PCBs.

Did the OP go through the alignment procedure? Did the OP bother with
antennas at all?

Did either of you read the kit doc?

Thanks,
Rich

wrote:

Thanks for all the hints. I have messed around with different receive antennas and I have finally gotten a usable picture. It kind of surprised me that I had to go through so much trouble at such a short distance. I am afraid I will never understand RF. At any rate, now my problem is with the audio (yes I have fiddled with all the adjustments in the transmitter). I cannot get the POPPING out of the audio. I phoned Ramsey and was told to exchange the 270 pf cap for a 220 pf cap. This cap is mounted on the underside of the board (see board drawing on the PDF). Well I will give this a try. I still wouldn't mind upping the power somewhat. I know there are resstrictions by I have no neighbors nearby. For some reason the schematic drawing is missing on the PDF. I do have the schematic that came with the instructions. Not that it does me a lot of good with my limited knowledge! Anyway, thanks everyone for the input.

Joe

Its my guess that the Transmitter has insufficient bandwidth and power
for that broad of a signal.
one must not forget the amount of band space a single channel takes.

I concurr. That transistor has the capability of putting out one watt,
though I don't think the circuit is designed to do that much. Even so, if
it is putting out even 100 miliwatts, that should get you several hundred
feet...with decent antennas. Once you are sure the circuit is operating
properly, work on the antennas . I did a TV transmitter of about 10 mw and
a really short whip antenna and got 20 feet no problem. Stuck it onto the
top of my camcorder and walked around the house. This was with the TV
"transmitter" from my 1970's "Pong" game and one of those broad band MMIC
amps...50 ohms in/out and a 18 inch whip above the camera. It was actually
in a Bud box with a home-made bracket that slipped into the light shoe. Had
to be a crummy antenna.

Just getting back into homebrewing and looking for the best sources of parts such as resistors, caps, boxes, etc.....

Right now I'm need of a source of MGFxxxx gaasfets.

Another question, is there a good online source where I can get specs on gaasfets, npn's transistors, etc.....

Message-ID: <ck1ne9ric1@newshost.mot.com>
Source record: 22862

1- The term "RMS power" has no mathematical or electronically correct meaning. It is technically meaningless. On the other hand, we often use terms to "imply" things within a certain circle. This is very common and accepted by many.

RAM is random access memory, but so is ROM (random access, that is) We all know what is meant.

Though Gary used the term "RMS Power" in his math description, It is a strange usage. Perhaps the "audio folks" coined it for some reason, but it is not a technical term in circuits, electrical Engineering or what ever you want to call serious electronics fields. HOWEVER, he did the correct math and he did enough explaining that it was clear what he meant by it. I maintain it is the meaning that is important and it is important to look past the differences in tech-speak some may have. Discuss the concept -- work to arrive at the meaning and don't quibble over terminology if at all possible. Too many time is see flames which jump between concept and terminology choice. Pick a common term and move on.

Not to long ago, it was common to call average power "true power". If circuit conditions are kept as they are for long enough, this is the power which goes wherever. I'll leave the philosophical (sp) discussion of just what power this is to Reg.

B- There is "Peak Power". Typically, this is the power at the peak of the waveform (often sinewave, but not necessarily). This power DOES occur at that time. The peak power is there. Voltage is there and current is there at the same time and power happens. For "Peak-to-peak" it ain't so.

There is never any peak-to-peak voltage which is present at an instant causing a peak-to-peak current to flow at that instant resulting in a peak-to-peak power.

B2 - We usually talk about the power over one cycle because that is enough time to know what it really is over the long term (assuming the wave sticks around for the long term)...

3- I disagree. An adjective or modifier isn't "needed" but it sure can help if there may be confusion as to just what the subject is.

D- What Gary said is true. "Once it becomes power it is no longer an rms value". This is because RMS values of voltage and current are simply tools we use to arrive at the true, average power...call it what you like We have to because there ain't no gizmo which measures the power directly (I'll ignore all the discussion about thermal means [or whatever] actually measuring the power).

5- What Gary said is false - "If it were really rms power then you should be
able to find peak power by multiplying by 1.414 as you do with rms voltage.
But that doesn't
work because power is not an rms value."
--- NOPE ---
RMS has a specific meaning (in this context) and it ain't in regard to
power. It is applied to the voltage and / or current when that is what you
want to use to find power. The part about "multiplying by 1.414" can not be
applied to power. This is an invalid extension of the math behind RMS...not
applicable...apples and oranges. Applying the wrong formula to the right
(or wrong) situation.

Only quantities which have been arithmetically derived by the equation -

P = Sqrt(Sqr(A) + Sqr(B) + Sqr(C) + . . .)

or its equivalents, can properly be referred to as RMS.

Occasionally, when there is something specially significant in the way a value been calculated, it may be descriptively convenient to precede its name with RMS.

But use of the term in a non-arithmetical context s meaningless.

The term 'RMS value' is also used in conjunction with other than electrical quantities, eg., as in Statistics.

Reg.

References:

Same one I gave before in an earlier post.
2000 ARRL handbook 6.6 chapter 6, RMS VOLTAGES AND CURRENTS. Read on
to the pep power paragraph too.

Here is another:
Here are quotes directly from: Electronics Pocket Handbook by Daniel
L. Metzger. Page 13.
This is a nice little book if you ever run across one pick it up.
About 280 pages.

Peak, Average and rms.

1. Use peak voltage or current to calculate maximum instantaneous
power only.

2. Use average current to calculate average power when the voltage is
fixed dc. Use average voltage to calculate average power when the
current is unvarying dc.

3. Use rms voltage and /or rms current to calculate average power when
the load is a linear device (resistor) and both V and I are ac in
phase and of the same waveshape. Use IV, I^2 R, V^2/R.

4. Rms measure is assumed in any ac voltage or current notation unless
peak, peak to peak, or average is specified.

5. The factor .707 for converting peak to rms applies to sine waves
only.

I didn't read the kit doc until just now. Not trivial for a beginner
to construct. Looks like fun, though. There are a lot of missteps in
the assembly / test procedure that could cause a "fuzzy" picture.
There are some useful hints for debugging though. Maybe there would be
a market for a better kit ...

I wonder if this transmitter complies with Part 15 regs?

Source record: 22869

gudmundur,

I found your April '03 usenet post about the SDK-85 monitor and was unable contact you by email. I have some SDK-85 stuff as well, and have recently pulled it out of storage for a self induced ASM refresher. Several years ago I 'OCR'ed a printout of the SDK-85 monitor, with comments, from my school days and managed to get it to compile in Pseudo Sam. It may still have a few typos but it runs. I also did a simple 9600 bps serial mod which seems to work well. I would be intersted in the stack problems and improvements you mentioned.

Any interest in sharing info?

Thanks,

bigk

2937. 500MHz wideband filter design

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-10-07 05:12:10 UTC
From: Joel Kolstad <JKolstad71HatesSpam@Yahoo.Com>
Message-ID: <ck2j70$b0i$1@news.oregonstate.edu>
Source record: 22870

I was curious if anybody had ideas as to how to deal with the fractional pF capacitors that come out of 'first pass' filter design programs such as Elsie for filters up in the 70cm (and slightly shorter) range (50 ohm terminations on both ends, LC style)? I'm attempting to build a bandstop filter up there (20dB attenuation, 10MHz bandwidth), and I'm aware of the usage of microstrip traces as equivalent capacitors (and inductors), but the filter needs to be (approximately) flat all the way back down to the ~30MHz and using, e.g., lamba/8 microstrip sections would create repetition in the filter's response every quadrupling of the center frequency.

So... other than attempting to be clever and transforming the filter such that capacitance is increased... or scaling the system impedance (to... 20 ohms? Then I'm still stuck with 2-3pF values)... are there any good methods of implementing such a wideband filter design at these frequencies? Pointers to books, magazine articles, etc. would be appreciated.

Thanks,
---Joel Kolstad

Bill, here's the story.

RMS and average are basic mathematical functions whose definitions you can find in numerous references(*). I'll state them here.

The average value of any periodic function is the time integral over a cycle of the instantaneous value of the function, divided by the period.

The RMS value of any periodic function is the square root of the average (mean value) of the square of the function, where the average is defined as above.

First, let's look at these two values for a sine wave with peak amplitude of V. The instantaneous value (value at any time t) is V * sin(wt) where w is omega = 2 * pi * frequency. The integral over a cycle is zero (since the wave spends equal amounts of time at equal amplitudes above and below zero), so the average value is zero. Some careless references will give a non-zero value for the "average" of a sine wave, but this is really the average of the absolute value (that is, the full-wave rectified value) of the sine wave. The actual average value of a sine wave with no DC offset is zero. (If it has a DC offset, the average value is simply the value of the offset.)

The RMS value of the sine wave is the square root of the average of the square of the original sine function, which is V^2 * sin^2(wt). If you graph this, you see that it looks like a rectified sine wave -- it never goes negative. If you go through with the math to get the average of this squared function, you get the nice value of V^2 / 2 for the average, hence V / sqrt(2) ~ 0.707 * V for the RMS.

Now let's apply that sine wave to a resistor and look at the power.

The *instantaneous* power, that is the power at any instant, dissipated by the resistor is v * i = v^2 / R where v is the instantaneous value of the voltage: v = V * sin(wt). So v^2 / R = V^2 * sin^2(wt) / R. Look familiar? So what's the average power? Using the definition of average, the average power is the integral over a period of the instantaneous power, divided by the period. In other words, it's average value of V^2 * sin^2(wt) / R. Looking at what we did to get the RMS voltage above, you can see that the average power is simply the square of the RMS voltage, divided by R.

That's why the *average* power is the square of the *RMS* voltage divided by R. It's important to realize that this holds true for any periodic voltage function -- square wave, triangle wave, what have you.

You can use the basic definition of RMS to calculate an RMS value of power from the instantaneous power, but it's not useful for anything. A resistor dissipating 10 watts of average power gets exactly as hot if that average power is supplied by DC, a sine wave, or any other waveform. That's not true of the RMS power -- different waveforms producing the same average power and causing the same amount of heat will produce different RMS powers. So average power is a very useful value, while RMS power is not.

The only thing that makes RMS voltage or current useful at all or worthwhile calculating is its relationship to the useful quantity of average power.

(*)You were asking for references -- you can find the definition of average on p. 254 and RMS on p. 255 of Pearson and Maler, _Introductory Circuit Analysis_, and average on p. 423 and RMS on p. 424 of Van Valkenburg, _Network Analysis_. You'll also find an explanation in both books similar to the one I just gave. These happen to be the two basic circuit analysis texts I have on my shelf -- you should be able to find the same explanation in just about any other circuits text.

Hello,

I need to built a simple, cheap antenna system for a 2.GHz audio-video link.
At the moment I'm just using thick wire as the antennas on the transmitter
and receiver. This system works surprisingly well... except for one little
glitch:

While moving the transmitter, I find there are small, highly localised
patches of space where the radio link fails completely. These "dead"
patches of space are only a few square centimetres in size.

I'm not a radio engineer so I'm not too sure what's going on. If I was
forced to make an educated guess then I'd say the problem was caused by
interference caused by reflected, out-of-phase signals. For example, it's
conceivable that the receiver could be picking up two 'copies' of the
transmission from the TX - one 'copy' is the direct signal, the other 'copy'
is a signal that has bounced off some surface - these two 'copies' would
cancel eachother out when they're 180 degrees out of phase.

So... this brings me to the question I posed in the subject line: why do
WiFi basestations use two antennas? For example, my 3Com basestation has
two little whip antennas sticking out the back. Are these two antennas used
to combat the problem that I am experiencing? If so, how can I implement
two antennas on my system?

If not, how else can I combat the problem I am experiencing?

A little more info about my system:
The system is part of a wearable camera with recorder. The camera,
transmitter, microphone and a battery are all worn in a hat. The receiver,
recorder and battery are worn in a bag. The system doesn't have to transmit
very far (only a few meters) but I do need the signal to be stable.

It's a technique called 'space diversity' that is also used in many radio
systems such as radio microphones and cellular radio. Two separate
receive aerials are used, on the principle that they are unlikely to both
be in a null at the same instant. There are various techniques to
implement this which range from simply coupling the two antennas together
to having entirely separate receivers and just selecting the best signal.
In your case it will complicate things considerably I'm afraid.

> parts such as resistors, caps, boxes, etc.....

Others have mentioned DigiKey - they are certainly my bread and butter parts source. Customer service is second to none, they have decent prices and most of the "normal" stuff. They are a little weak, however, on RF parts.

Dan's Small Parts and Kits http://danssmallpartsandkits.net has a lot of the hard to get stuff, and generally at very, very good prices. However, he only takes orders by snail mail, so with the post office being used in two directions, you need to be prepared to wait a while.

W8DIZ http://partsandkits.com has a selection of toroids, and assorted other parts. He doesn't have a lot of stuff, but what he does have is usually at very good prices.

BG Micro http://www.bgmicro.com has a changing collection of stuff. Sometimes you can get very good deals on things like LCDs, cases and switches. They tend to be the high-priced spread on crystals and IC's, however. Also, sometimes their stuff is surplus or pulls. Be sure to read carefully.

For hardware, Mendelsohn's http://www.meci.com is a great source. They have some pretty strange stuff and their collection changes all the time. Like BG, for some things they seem to be a little pricey, but for others, they can't be beat. If you get a chance to go to Dayton, plan on bringing back many pounds of nuts and bolts from these guys. Typically they will sell many hard to get little bits by the pound.

If you need some RF thingie badly, RF Parts http://www.rfparts.com is sometimes the only place. They seem to have the highest prices on the planet, but if you need a high power RF transistor or a transmitting cap, there may be no other source.

> Another question, is there a good online source where I can get specs on
> gaasfets, npn's transistors, etc.....

Poke the part number into Google. Generally it will return links to datasheets in more languages than you knew there were.

> Hi Joel,
Perhaps you can give us some additional number? What sort of attenuation
level do you require? Where are the -3dB corners? What is the tolerbale
passband return loss?
You mention the filter needing to be good down to 30MHz, but no mention of
characteristics above 70cM. A 10MHz wide bandstop filter with decent
attenuation at 70cM is going to be complex. Would perhaps an elliptic LPF
also work? Do you need the full 10 MHz of stop frequency?
I use the Genesys simulator/synthesizer package which is highly flexible,
allowing real time filter tuning- but ALWAYS try to avoid a wide spread in
component values and very small capacities.

2944. Noise Figure Measurements

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-10-07 13:19:24 UTC
From: skavanagh72nospam@yahoo.ca
Message-ID: <5249fb3f.0410070519.2a1d4f3a@posting.google.com>
Source record: 22878

I've been playing with trying to make rough noise figure measurements on the cheap and have a couple of questions:

(1) Are there any issues with the following setup and procedure for making relative noise figure measurements (e.g. comparing two receivers) ?

Procedure:
(a) For receiver 1 connect a high impedance AC voltmeter to the audio output marked "0 dB". Record voltage with noise source off.
(b) Turn noise source on and measure AC voltage at "-3 dB" output. Adjust step attenuator to get same voltage as in step (a). Record step attenuator setting.
(c) Repeat steps (a) and (b) for receiver 2.
(d) The difference in noise figure between the two receivers is the same as the difference in attenuator settings recorded in (b) and (c). For example if the attenuation for receiver 1 is 10 dB and for receiver 2 is 12 dB, then receiver two has a noise figure which is 2 dB less than that of receiver 1.

Assuming this is OK we move on to question 2:

(2) To avoid the expense of a calibrated noise source, I wonder if the repeatability from unit to unit of simple low noise amplifier circuits (perhaps a MAR-6 ?) is good enough to allow one to be used as a noise figure standard, at least for fairly rough measurements at HF and VHF. I am hoping that accuracies of +/- 1 to 2 dB might be achievable. Has anyone measured the NF performance of simple MMIC amps at HF & VHF ? Or looked into noise figure repeatability ?

I am looking for a handheld Spectrum Analyzer BK2650 (Link1 below) or Field Strength Analyzer Protek 3290 (Link2). The problem is that I cannot see the major differences between them, yet there's a major price difference of $1000-2000. Can anyone tell me what the major differences between a spectrum analyzer and Field Strength Analyzer? Is it in demodulation ways, sweep speed, display freq span, or some extra stuff that I do not need as an amateur/electronics hobbyist? Thanks.

What order filter (how many capacitors)? What sort of power level?
Guess I'd look at trimming the capacitances. I have a bunch of
0.5-5pF trimmer caps that I might use for such a filter. Or, I'd get
a big pile of 1pF, 1.2pF, 1.5pF, ...etc and select caps that measured
correctly. Since 10MHz really isn't a very big percentage bandwidth,
I'd probably go for trimmer caps, and tune the whole filter using a
network analyzer to monitor its response. Does your filter design
program give you the resonant frequencies of each resonator? -- Does
your design not have some really small inductances, too??

Cheers,
Tom

Off-the-cuff, I'd suggest that one large reason for the price difference that while B+K Precision is a pretty 'well known' US company (not in the same league as, say, Fluke, but close), Protek is a Taiwanese company that is nowhere near as well known. Their manufacturing costs may be significantly less as well. I have a "GC Electronics" brand power supply that's a virtual clone of a Tektronix power supply... it cost something like $600, while the Real McCoy was more like $1300!

I'll be curious to see what others have to say...

> What order filter (how many capacitors)?

Looks like I can get away with a third order; just a pi or tee.

> What sort of power level?

1W.

> Does your filter design
> program give you the resonant frequencies of each resonator?

Yes, or at least I can calculate it readily enough.

> Does
> your design not have some really small inductances, too??

They're in the 'hundreds of nanohenries' range. With them I've been more worried about obtaining decent Q's than the actual values, in that parasitics would seem to be much more comparable to the size of the caps than the inductors.

Thanks for your advice,
---Joel

Bill,

If you read carefully in any of the handbooks where they discuss the
resistor heating by AC compared to DC you will see that they say "RMS
VOLTAGE that causes the same amount of heating in a resistor as the
same amount of DC voltage". They do not say the same amount of RMS
power.

Since a constant DC voltage would equate to average power in a
resistor, then if the same amount of AC RMS voltage causes the same
amount of heat it has to also be average power that it produces.

Another issue you'll have to deal with if you don't do some scaling of some sort is that the inductors that go with the fractional-pF capacitors will have significant parasitic capacitance...you're likely going to get self-resonant frequencies not far above the filter stopband frequency (or worse). It would help a lot if you could make the filter stopband considerably wider. Seems like with a 10MHz stopband, you're asking for filter performance not too unlike a duplexer.

You mentioned the need for the filter to be flat down to low frequencies, but what about higher frequencies? Are the repetitions which are common in distributed (transmission-line) filters really a problem? Or do you need to pass all the higher frequencies too?

Cheers,
Tom

I'd be interested in where you've read this. It's wrong. I suspect that
if you go back and read carefully, you'll find that it's the RMS value
of the voltage or current that causes the same heating as the same DC
value, not the RMS value of the power.

Incidentally, I should mention that "RMS power" is used by the makers of
audio amplifiers. About four years ago, this topic came up on
rec.radio.amateur.antenna, and Jim Kelley commented about it:

Jim Kelley wrote:

> I found out the answer to this usage of RMS power. The audio folks
> have co-opted the RMS idea to mean the following: If the signal is a

> completely flat on peaks that are only a little greater than the RMS
> rating. Anyway, the use of the term is pervasive.

So the term is sometimes used in the consumer audio world, although
incorrectly. One shouldn't look to the audio consumer world for accurate
technical information about anything.

> In your
> statement above, you say that's true only for average power, not RMS,
> and is true for *any* waveform, including sine waves.

Let me demonstrate my statement about the average power being the square of the RMS voltage divided by R for any waveform.

Call the voltage time waveform v(t). This was V * sin(wt) for my sine wave example, but let it be any periodic waveform. The RMS value of the voltage Vrms is, by definition, sqrt(avg(v(t)^2)). Applied to a resistor, the power time waveform p(t) is v(t)^2/R, so the average power is avg(p(t)) = avg(v(t)^2/R) = avg(v(t)^2)/R. (The 1/R term can be moved out of the average since it doesn't vary with time -- the time average of 1/R = 1/R.) From the definition of RMS voltage, you can see that avg(v(t)^2)/R is simply Vrms^2/R. This was demonstrated without any assumption about the nature of v(t) except that it's periodic.

The RMS power caused by that v(t) waveform would be sqrt(avg(p(t)^2)) = sqrt(avg(v(t)^4/R^2)) = sqrt(avg(v(t)^4))/R. This is different from the average, with the size of the difference depending on the shape of the waveform.

> Is there a new world order?

No, but hopefully there's some new knowledge being gained.

Source record: 22896

Making a basic spectrum analyzer isn't very hard. What's hard is to make one that has a high dynamic range while at the same time maintaining a decent noise figure, and one that's free from spurs. Filter quality (slope factor) and number of bandwidth options are areas that were expensive and therefore often slighted, although that's probably done now with digital filtering. I'd take a close look at those specs, and be cautious if they're absent. There's a reason the well known companies are well known. They've earned their reputations by producing quality equipment that always meets the advertised specifications.

Sorry, while I know just what a spectrum analyzer is, I don't know about a "field strength analyzer".

True. But at twenty bucks for a 2SC1968 it's pretty easy to reach $25!

DigiKey has, or maybe used to have, a fee for orders under $25, but they have so much stuff I can't live without that it's never an issue! Most places are going to charge $5-$10 for shipping, too, so tiny orders are a problem anyway.

One thing I should mention with DigiKey ... look at the shipping options and specify what you want. Their "default" seems to be 2nd day air, which can be pricey. Where I am, it sometimes saves a day, sometimes not, so at least for me, it's never worth it. But if you have to have that part tomorrow, DigiKey will ship it today if you call them before 8 PM Central time.

Once I ordered a part from them that needed special programming. Their programming person had left for the day so they were all in a panic when they realized they couldn't ship that evening. I told them it wasn't a big deal, but at 10 the next morning they called again to assure me that my $3 part had made it onto a truck.

Yes, I can definitely appreciate that.

Well, it's supposed to be an adjustable notch filter, from 30-500MHz, with a 2% stopband width... and it's at the high end where it's looking pretty challenging.

> You mentioned the need for the filter to be flat down to low
> frequencies, but what about higher frequencies? Are the repetitions
> which are common in distributed (transmission-line) filters really a

At the higher frequencies, no. At lower frequency, yes! This might suggest breaking it up into two filter, since I could probably get 300-500MHz out of distributed filter. The problem there is how to set the center frequency... although simply using PIN diodes or similar to ground the transmission line somewhere along its length sounds promising.

> Bill W6WRT

Oh, I suppose, but I maintain this is something you determine within the discussion, then move on to cover the important aspects of the issue at hand. After moving on, you won't have to keep saying "Average Power' (or whatever is decided upon) each time you want to refer to it. You will just need to say "power", since you have defined the term. This is a semantic-fest, rather than a discussion of how to determine power. I've been in many, many discussions, where once the subject is defined, the word "power" is used repeatedly, never with any adjectives and no one had any problems.

You guys are too tied up in what is "official". It is what is in common usage that matters. define your terms and move on.

What is official to you? It appears you are not sure what the word
'average' means.

Ask Jeeves gave quite a few official looking references for a search of
"average power"
http://ask.com/
See the ones that look like dictionaries of glossaries.

See the "graphics version":
http://www.abdn.ac.uk/physics/bio/fi20www/tsld016.htm

A search via Google and some poking around just gave me:
hyperphysics.phy-astr.gsu.edu/ hbase/electric/powerac.html
http://mitglied.lycos.de/radargrundlagen/primaer/pr22-en.html

http://www.twysted-pair.com/dictp.htm

http://www.csgnetwork.com/ohmslaw2.html

Power used by the human body on this one:
http://www.csgnetwork.com/ohmslaw2.html

Look Ma, No adjectives:
http://www.ffldusoe.edu/Faculty/Denenberg/Topics/Electronics/Alex_Pounds/Section6-10.htm#P
ower%20&%20%20energy

This should confuse you even more.
http://www.tpub.com/content/neets/14192/css/14192_15.htm

Then I found this !!
Looking for average power? eBay has great deals on new and used electronics,
cars, apparel, collectibles, sporting goods and more. If you can t find it
on eBay, it probably doesn t exist.

Bill,
Please be careful here. You are confusing yourself. The passage you
quoted here is indeed correct, but I believe you are interpreting it
incorrectly because you are thinking of the term "RMS Power" as the "loosely
defined" term in the audio world also spelled "RMS Power".
The above passage is indeed correct IF you understand that it is
referring to an RMS value of the power waveform. (one of the links I posted
previously shows a power waveform in the "graphics version" link) This is a
mathematically defined "Root Mean Square" value of the power waveform. THIS
does indeed have no use. Calculating the Root-Mean-Square of a power
waveform does NOT produce the average power we think of as heating the same
as DC. We don't do it and in the Engineering community we don't use that
term at all. We talk about the 'true' or 'average power' to make things
clear, if needed.
However, the term bandied about in Audio circles which is also spelled
"RMS Power" means something completely different. One term - two meanings.
It has been used (as I gather from earlier posts) to mean what would be
correctly describes as: the average power produced by a channel of an audio

amplifier under sinewave signal conditions. This describes what is technically called "Average Power", but the audio folks saw a need to have something to hang their hat on we=hen talking about this measurement and, unfortunately picled something just to confuse you, Bill.
This is two different uses for the same phrase. The first is a mathematically defined value (the same math used to get RMS voltages) and the other is a commonly accepted meaning in a specific field.

Both can be correct IF you understand which deffinition is in use.

I agree also that the second antenna is for diversity but none of the
manufactures can answer why it is needed if spread spectrum is suppose to be
so innately fade resistant, even though the spread spectrum Wifi is using
now with CCK isn't really truly random anymore.

Agreed, the Digi-Key guys are hardcore. I once posted a message to this
group criticizing the company for using expiring tokens in their part-
lookup URLs, and they actually saw it and responded to the criticism
with a workaround.

Digi-Key is not the cheapest vendor out there, but they set the standard
for everyone else to follow when it comes to service. It's not unfair
of them to charge extra for orders under $25. I don't want them losing
money on MY order (not that THAT will ever happen).

With very short direct and reflected paths typical in indoor
installations, you are not going to have multiple nulls within the
spread frequency range. In order for a spread spectrum system to work
properly in a multipath environment, there should be several multipath
nulls within the spread range. If there is only one wide dip covering
your spread range, it can take out most of your signal.

If the spread range is from say 2400 to 2430 MHz, the corresponding
wavelengths would be 125 - 123.5 mm so the spread in wavelengths is
1.5 mm so you would need at least a path difference 40 wavelengths or
5 m to get a phase difference of 180 degrees that would cancel the
signal at one end of the spread range but add up in the other end.

With a larger frequency spread or larger path distance between the
direct and reflected signal, the phase difference would be several
times 360 degrees and there would be multiple nulls (at 180, 540 etc
degrees) and multiple peaks, within the spread range, which the spread
spectrum modulation could easily tolerate.

I'm think it's more a question of consistency. If you define RMS voltage and current a certain way (that we're all in agreement with), it stands to reason that "RMS foo" should have a comparable definition. As Roy has shown, using that same definition makes "RMS power" of questionable utility.

The fact that 'the audio guys' don't use that definition is unfortunate and something to be aware of, but arguably not something to be encouraged. :-) (On the other hand, getting the audio guys to agree to _any_ definitions can be dicey... their usage of 'RMS power' was motivated by other terms such as 'PEP' -- peak envelope power -- that have almost nothing to do with the utility of the amplifier whatsoever. It's not uncommon to see '100W PEP' amplifiers that come with little wall warts capable of delivering no more than, say, 3W average power.)

Hi Ian
Here's a link to a real nice dual-band j-pole that's easy to build.
http://www.arrowantennas.com/j-pole.html
copy the element lengths off this page (or print the page out) and then
click on INSTRUCTIONS
on the bottom of the page for the rest of the info. Has excellent swr across
both bands.

Certainly there is such a thing as RMS power. It just isn't useful for anything. The definitions I used aren't arbitrary at all, but widely accepted and agreed upon. It's true that some amateurs and consumer audio marketers have chosen not to use the accepted definitions, but their inventions shouldn't be given equal weight to ones which have been used for centuries and are universally accepted by the math, physics, and engineering communities.

What's the problem with current flowing from plus to minus? I believe it was Ben Franklin who realized that there are two polarities of charge, and arbitrarily called one plus and one minus. If he had made the other choice, positive or negative charge would indeed flow the other way.

I've been through technical school, where current was considered to flow from minus to plus, and engineering school, where the opposite definition was used. You can use either method and arrive at the correct answer, but you end up with quite a few more minus signs with the minus-to-plus convention. Since engineering is highly mathematical, the plus-to-minus convention makes sense for engineering because of the somewhat simpler equations that result.

I've always thought that tech schools used the minus-to-plus convention because it made it easier for students to get an intuitive feel for how a vacuum tube operates. (It's hard to imagine positive charge leaving the plate and condensing on the hot cathode!) Now that fire-fets are (like some of us) largely relics of the past, and the importance of good communication between technicians and engineers is recognized, I'd be surprised if the minus-to-plus convention is still being taught even in tech schools -- if anyone has any recent information about this, I'd be interested to know.

You may be reading what people wrote but you are doing selective
reading. You are only letting through things that agree with your
preconceived beliefs and blocking out the logic.

You have the bandwidth cranked in too tight, the notch filter set too
deep on the wrong side of the pass band and the noise blanker on. You
are complaining how bad the signals sound but if you read the manual
you may be able to clear the problem. :>)

Roy said that there is rms power but that it has nothing to do with
average power that we get when rms voltage and current are multiplied.

I and others have said that there is no such thing as rms power. That
is not a stand alone absolute fact obviously but in this context it is
meaningless.

You can find the rms value of any periodic wave just like you find the
rms value of voltage or current. But finding the rms value of power is
of no value. And you don't get it by multiplying rms voltage by rms
current. Again, once you multiply an rms value by another rms value
the answer you get is not rms.

Rms is not a title. It is the result of a mathematical operation.

Average power and rms power are not the same.

It's too bad you've chosen to limit your thinking in this way, but as long as you can fit everything that interests you into the box you've created, I guess it doesn't cause you any problems. I'd think you'd have to avoid such topics as lightning and positive ion generators, though.

It's a common mistake to equate "current" or "charge" with "electrons", but probably no more common than lack of understanding of what RMS and average mean. A lot of people seem to manage to maintain a more-or-less consistent view of electricity while carrying around some pretty mistaken ideas. In my experience, though, now and then they end up really stumped by something, while someone with a more complete view of basic electrical physics has an easy time understanding and analyzing what's going on. We all make our choices.

NOW AVAILABLE ** New Program "TRAP3.exe"

This program calculates the performance of an antenna trap. It also assists with selection of trap capacitor value, coil length and diameter, and number of turns. For full design of a trapped dipole use in conjunction with program TRAPDIP.

An independent signal generator is built into the program. It generates a testing frequency which allows the traps's performance, input impedance versus frequency, to be 'measured'.

One small file, size = 43 kilobytes.

Have you ever wondered what your traps are really doing? Download program from website below in a few seconds and run immediately.

Hi Tam,

Actually, the ones that looked easiest to use were the 1210 case size. I ordered some from mouser yesterday. I hope they're big enough for me to see.

I was wondering about a post I read somewhere else a long time ago. Is there such a thing as a paste (that comes in a tube) that can be applied to the terminals of a surface mount device and then when it is stuck to the board, the paste hardens into something like hardened solder? So it is mounted to the board and soldered with this paste?

One-part conductive epoxy fits that description. It's commonly used to mount SMT parts on hybrid circuits. However, the ones I'm familiar with require curing at an elevated temperature (e.g., 150C for an hour). I believe there are also some UV curing conductive epoxies. Conductive epoxy can be used for mounting parts on a PCB, too, but I don't think it's commonly done because it's considerably more expensive than solder. There might be two-part conductive epoxies that cure at room temperature, but I've never used one and am not sure they exist. The one-part epoxies I've used aren't conductive until they're cured -- the tiny conductive (gold or silver) particles in the paste don't contact each other until the curing process causes the epoxy to shrink and pull them together.

Then there's solder paste, nearly universally used for mounting parts on PCBs. This also fits your description and can by applied by hand with a syringe, then melted by a number of means -- hot air, IR, soldering iron. It's actually a slurry of flux and tiny spheres of solder. It's not really sticky, but sort of gummy, so some other means (like superglue) has to be used if the parts need to be kept in place when the board is inverted or severely disturbed before the paste is melted.

Cheap calibrated noise source, 35dB Bandwith 100kHz - 500Mhz.
http://www.elecraft.com/manual/N-gen%20man%20rev%20C.pdf
Noise performance of Mar's MMIC's should be noted on datasheets.
I have them "somewhere", with a little luck Google finds it too.
You can measure and calibrate your own noise generator.
Terminate receiver with 50 Ohm resistor, measure output and label it
zero dB.
Remove resistor, and switch ON the unknown ENR, Z = 50 Ohm.
The only thing to do is, ATTenuate in steps until you are at first measured
output labeled zero dB.
Add simply the dB's of the ATT units, this should be the ENR dB's.
Please correct me if I am wrong.
Homebrew ATTenuator pads can be build low as 0.1dB accurate enough.

Sources of how to measure NF are radio amateurs who do EME.
Google should come up with data if you search at "low noise" "EME" etc.
PS: Google for VE3DNL Using Noise Generators to measure Noise Figure.
Greetings Bas.

Wow, I ran across this post by accident, Yes, I am still in the states,
and just wrote some programs for re-formatting NMEA marine nav data
strings. I kept most of the second kilobyte intact, with changes mostly
to the soft uart for 4800 8N1, and extensively modified the first 80
bytes of stack push/pop locations right up at the beginning of the first
kilobyte. Used the remainder of the first K for my datastring parsing.
Have 2K of ram on my little unit (not the original SDK motherboard), and
I can write little parsing mods in ram to test them. (I work with
Raytheon older nav equipment, and radar gear, it is my specialty)
I use the SDK tiny clone to do things like have my Delorme TripMate
drive my 700L Loran chartplotter.

Did you actually do 9600 baud using the soft uart SID/SOD? I thought
my 4800 was really pushing the limit for sustained data bursts of
1 or 2 kilobytes. It was hard to get the timing of the bits just right.
A little bit fast, or slow, and things slip out of sync after a few
hundred bytes.

Hams at UK rallies typically tend to smell rather badly, too. And look
like child molesters. Is this a world-wide phenomenon or a purely
British one?

Must be purely British as no other country seems to have the
paranoia we seem to have about child molesters.

One last try...

When you look at the history, "current" and "flow of electrons" truly
are two different things. They come from two different centuries of
science and engineering.

"Current" came first. As people invented electrical devices such as
batteries, electromagnets, motors and generators, the concept
developed that "electric current" must in fact be a flow of charged
particles.

However, you can't experiment on a battery without labeling the
terminals, so the convention that "current flows from positive to
negative" had to be established very early (by Faraday, I believe).

The new technology of electrical engineering forged ahead for several
decades without ever needing to know what those fundamental charged
particles were. Faraday himself never knew. When the electron was
finally identified, it was found to have a negative charge - which meant
that what people had been calling "current" is actually a flow of
electrons in the opposite direction.

But by then there was absolutely no question of changing the conventions
of what "current", "positive" and "negative" mean. Those conventions
remain unchanged to this day.

That was how we were taught it in school, at age 12:

"Here's all the history" (as above, only with dates... which I've
forgotten).

"Hard luck that the electron turned out to have a negative charge. It
makes life a bit more complicated."

"'Current' is not the same as 'flow of electrons', because they're going in the opposite directions. Be careful to say the one you actually mean."

"Don't worry, you'll learn to cope with it" - and so we did.

It's only hard if you insist on *making* it hard.

Message-ID: <10mgbm33q2pdt24@corp.supernews.com>
Source record: 22787

It's a universal tendency for people to simplify things in order to understand them. That's fine, as long as they realize that their understanding is based on a simplification, and they don't try to apply it to areas where the simplification is no longer valid. While the idea of charge flow as electron flow works just fine in a vacuum tube, it isn't at all true in general.

Current is the rate of flow of charge, which as I'll explain isn't the same as the flow of electrons. Charge can be positive or negative. A shortage of electrons in an atom's valence shell results in a positively charged atom (a positive ion), and an excess of electrons in a negatively charged one (a negative ion). In a conductor, electrons are quite free to move about. In a semiconductor, they're not, and the crystal lattice can contain either an excess of electrons (N type material), a deficiency of them (P type material), or a normal number (intrinsic material). In a vacuum tube, the flow of (negative) charge is simply the physical flow of electrons, and the flow of positive charge becomes a mathematical concept, moving the opposite direction. But this isn't necessarily so in other media. In a wire, for example, charge flows much faster (near the speed of light) than electrons (which flow at a rate on the order of a few miles per hour). If you jam a bunch of electrons into one end of a wire, an equal number very quickly pops out the other -- but these aren't the same ones that went into the other end -- those will slowly drift along the wire at a few miles per hour. The rate of charge flow is dictated by how long it took electrons to pop out of the other end of the wire after jamming some in the input end, not how long it takes the added electrons to drift their way along. So in a wire, for example, charge isn't the same as movement of electrons. If you try to envision physical current (charge flow) in a wire as being the same as physical current in a vacuum tube, you'll be misleading yourself.

Now imagine sucking a bunch of electrons out of one end of the wire. There'll be an electron-poor region at the wire end. A "wave" of electron-poor region will propagate to the other end of the wire at nearly the speed of light, and a bunch of electrons will be sucked into the other end of the wire. The propagation of this wave of an electron-poor region is the physical flow of positive charge. Envision, if you must, sucking water through a drinking straw that's already filled with water. Bear in mind, though, that this isn't an exact model of what's happening, so be careful in using it.

It's important to be able to separate the concepts of moving charges and moving electrons, if you're going to have the versatility of understanding things other than vacuum tubes, like positive ion

generators, lightning, charge flow in a semiconductor, or even a wire. Once you do, it becomes just as easy to envision positive charge flow as negative charge flow. If you can't do this without imagining physical marble-like particles carrying the charge, you have no hope of understanding an electromagnetic field, or other more abstract and mathematical concepts.

Roy Lewallen, W7EL

-- A quick web search brought this brief explanation of how electrons behave in a conductor: http://hyperphysics.phy-astr.gsu.edu/hbase/electric/ohmmic.html. I'm sure it would be easy to find a lot more good information (as well as some pretty bad stuff) if anyone is interested enough to look.

As a UK amateur who attends rallies (not "ham" please, it makes me sound like something off the butcher's slab..!) I take offence at that. I don't look like a child molester, at least nobody has ever told me I do. Nor do I smell.

Please retract your statement forthwith.

I certainly will not! I'm also a UK amateur/ham who attends rallies so
the slur is equally applicable to me as well. The remark is a
generalisation, of course and doesn't apply to every single ham in the
country. Just a significant proportion. But I dare say the same could
be said for train-spotters, real-ale enthusiasts and stamp collectors.

Thanks Roy,

It sounds like the solder paste is what I heard about. Sounds easier than
trying to solder such small parts with an iron. I will see if mouser carries
it and give it a try.

==========

The universal tendency on this newsgroup is to overcomplicate things to further confuse matters. (If that's possible).

There's nothing better than a very few carefully chosen words of plain, simple, factual English language.

Responders should very carefully edit and summarise what they have to say before hitting the 'send' key.

I hasten to say, Roy, you certainly do not fall into the 'careless' category.

I am at present on Californian red Zinfandel. Where it got its name from I can't imagine. But on the side of the bottle it says it should be consumed within 1 year of purchase. There is still 364 days to go.

Correction:

The speed of electron flow in a conductor is more like a few feet per hour rather than a few miles per hour as I said, at reasonable current levels and wire sizes (but depending on the current and the wire diameter). The numerical example for copper shown at the web site I mentioned shows an electron drift velocity of 4.3 mm/s for a 1 mm diameter wire with 46 A current (which would probably explode the wire). This works out to about 51 feet/hour. At the more reasonable current of 3 A, the electron drift velocity drops to 0.28 mm/s, or about 3.3 feet/hour.

The electron drift velocity is so slow because, even though an ampere of current is a seemingly staggering 6 X 10^18 electron charges per second, there are vastly more free electrons than this in even a small wire. (Again see the web site example, where the density is shown to be about 8.5 X 10^28 electrons/m^3, or about 6.7 X 10^22 electrons in the 1 mm diameter, 1 meter long wire in the example.)(*) Carefully using the drinking straw analogy again, imagine a very large diameter drinking straw (lots of free water "electrons"), where an ampere of current is represented by a tiny trickle of water. If you suck water out one end at the rate of "one ampere", it takes a long time for the actual water molecules at the other end of the straw to work their way up the straw.

(*) You can, in fact, calculate the drift velocity somewhat more simply and perhaps more intuituvely than the author of that page did, knowing only the electron density and the size of the wire. From the wire size you can calculate its volume as 7.85 X 10^-7 m^3. Multiplying this by the electron density, you get the total number of free electrons it contains, about 6.7 X 10^22. So the wire holds 6.7 X 10^22 / 6 X 10^18 ~ 11,000 coulombs (ampere-seconds) of available charge. If we move charge through at the rate of 46 amperes as in the first example, it would take 11,000/46 ~ 240 seconds for an electron to move from one end of the wire to the other, a rate of one meter/240 seconds or about 4.2 mm/sec. Within roundoff error, this is what the author calculated.

Faraday established the convention that "current" flows from "positive" to "negative" in 1834.

Thomson discovered the electron in 1897, and found it had a negative charge.

But even then, it was already far too late to think about changing the convention about "current". Scientists who had to work with electrons would have to learn to live with it.

And if it was already too late in 1897...

>Not a big deal, but it is fascinating to me how nobody will take the
>bull by the horns and fix it.
>
There really ain't much that's needful of fixin'. Electrical engineering was growing and thriving before electrons were discovered, and a century later, everything still works. Even "electronics" hardly ever has to think about electrons, or the sign of their charge. We're doing just fine, thank you.

It's an untidy world, Bill. Please get over it... soon :-)

3002. GPIB-ENET control software

Newsgroup: rec.radio.amateur.homebrew

Hi all,

Recently I acquired a GPIB-ENET controller. It appears to work. With this interface I want to control RF equipment. I can buy NI official software, but first I want to know if there's any shareware available, possible in the scientific world.
Please advise.
Regards,
Harke, PA0HRK

Perhaps if you posted the proper schematic it would help. What's the
transistor in question?

Yes, that's what you'll be telling you lawer when you've been done for
kiddie porn. (joke)

But, seriously, that sort of evolutionary psychology is fatally flawed. The
most glaring problem with it is that we're social animals - what makes us
humans different from all other animals is our ability to share thoughts.
What makes humans such a powerful (or lethal, depending on your perspective)
species is that we no longer have to wait millenia to evolve new faculties -
we can evolve *culturally*, which is orders of magnitude faster than
biological evolution.

So, what I'm getting at is that there are loads of reasons for associating
with other people other than to get your end away. What we're doing right
now is an example - we all feel compelled to share our thoughts on these
news groups without any desire to have sex.

Jack.

Thanks Michael,
I'm sorry I can't post the full diagram as my scanner's bust. I'll try
to clarify. I know why the base of the transistor (it's a 2n5771, in
answer to Paul's question) is at DC ground. I'm not so dumb as to
realise that a choke passes dc but not the high frequncy RF. I guess
it boils down to this: how did the designer arrive at the given value
of 0.4uH for this inductor? Why not 4nH? Why not 40uH? Why not 100mH??
What's the deal with this value and since I've only got a 1uH in my
junk box, will that be okay instead?

Thanks, all,

Steve.

it looks /IIRC schematics posted/ that that is a some kind of RF power
amp in "C" class ....

that inductor keeps shorted transistor base for DC to ground &
capacitor keeps away DC from previous stage.

Also that CR circuit is an impedance transformer (from previous higher
to transistor lower RF Z input & also a high pass filter @ the same
time.

If enough RF current would pass capacitor to rise the potential over
few hundred mV RF, every half-period of the signal will open
transistors E - C gate to conduct thru (parallell) LC tank that
should be connected there from C transistor terminal to power line.

LC tank will recover after one period also other (opposite)
semiperiod, so you will have a complete sinusoide (RF) to transmit (or
amplify it further).. usefull only for CW, modul.CW or FM (not AM or
SSB).

Hope I helped & understood the schematics & question.

Reg is right, but it's an oversimplification. The contact can be
indirect for the purposes of self-propagation. You might not want to
shag the person you're shaking hands with, but you presumably want to
make a good impression on them. Maybe it's a job interview; maybe
you're making a new friend; whatever. The motivation (usually
subconscious) behind the gesture is to better your chances of
replicating yourself; increasing status/wealth-generation/social
standing, whatever, are means to a successful biological end.

> What's the deal with this value and since I've only got a 1uH in my
> junk box, will that be okay instead?

I'm guessing you're not experienced enough to realize that inductors are far from ideal. Among their many imperfections, the most problematic in an application like this is shunt capacitance. This resonates with the inductance to create a parallel resonant circuit. At resonance, the impedance is very high -- higher than that of the inductance alone. But above the self-resonant frequency, the impedance drops, and at some point becomes less, then very much less, than the impedance of just the inductance. Well above self-resonance, all you see is the self capacitance -- it looks like a capacitor, not an inductor.

That's why a designer doesn't just use 100 mH for everything. Just about any 100 mH inductor looks like a capacitor at 145 MHz, with a very low impedance, much lower than an inductor with smaller inductance value.(*) The trick is to choose an inductor that's below or at its self resonant point while still having enough impedance so it doesn't disturb the circuit it's across. A good rule of thumb is an inductor whose reactance is about 5 - 10 times the impedance it's across. (In your case, this might not be easy to determine. You might be able to get it either from knowing someting about the previous stage, or from the S parameter specfication of the transistor.) 5 - 10 times is usually enough, and if you try for too much, it won't work any better and you run the risk of being above the self-resonant frequency. Of course, an individual inductor can be measured to make sure its impedance is high enough at the frequency of use, if you have the equipment to make the measurement.

So, now, is your 1 uH ok? It depends on its shunt C, which depends on its construction. If you can't measure it, just try it. The worst that's likely to happen is that it'll kill the signal (due to low impedance). At only 2-1/2 times the value of the original, there's a good chance it'll work ok. If it doesn't, and if your 1 uH inductor isn't potted, you can get the value down to 0.4 uH by unwinding about 1/3 of the turns.

(*) Even this explanation is highly simplified. At higher frequencies, the inductor will exhibit additional series and parallel resonances due to various parasitic capacitances and inductances and transmission line

effects.

>junk box, will that be okay instead?

Well then it appears Reg's hunch was right. The transistor in question
has an input capacitance of just under 3pF, so the 0.4uH inductor
forms a parallel tuned circuit with it at 145Mhz. This prevents the
input signal from partially shunted to ground via the input
capacitance were the inductor not there. The idea is to allow as much
of the input signal as possible to develop across the BE diode to
maximise input impedance and gain. The input capacitance is in
parallel with this diode and bypasses RF signals around it - which you
don't want. Will a 1uH work instead? Do the maths and find out. But
if you don't know the inductor's Q that probably won't help much...

The problem is, there are quite a few possibilities for what the inductor
is doing. For example, it might be providing a DC path to ground for the
base of the transistor, or it might be supressing a parasitic oscillation in
the amplifier.

Or, for that matter, it might be part of an impedance transform from one
section to another. Without the complete schematic, there is no way to
tell.

> nothing!

The circuit is simple enough that a schematic isn't all that necessary. At the same time, I can see that there's very little that can be done to boost the signal, short of adding components. This would be, if investigated by the FCC's enforcement of unlicensed radiators (in excess of Part 15 regs) evidence that the user was in violation of the "intentional radiator" limits under Part 15.

> I would try better antennas before hacking the TV6.

The manual goes to some length to describe the expected coverage area for this device. I'm with you that Joe has some issue with antennas (and again, please note that putting an antenna with gain would suggest that the user is intentionally violation Part 15). Is there a set-top antenna being used? Is the feedline from the transmitter unit undamaged, and properly connected? Is there a balun being used to match the 75-ohm output to a 300-ohm folded dipole?

> BTW, you are shamefully crossposting to too many newsgroups!

I show the list of only 5 groups....not excessive, but more than I usually see without it being tagged (and glommed) as spam.

I think the question is why should engineers, who have designed everything from communications satellites to cell phones to the computer you're using, your ham radio rig, and countless other things over the past couple of hundred years, change their methods? Because Bill isn't able -- or willing -- to understand the difference between charge and electrons?

Sorry, you haven't managed to convince even one engineer, and you've got millions to go. Good luck.

@yahoo.com says...
> Hi all,
>
> Recently I acquired a GPIB-ENET controller. It appears to work. With this
> interface I want to control RF equipment. I can buy NI official software,
> but first I want to know if there's any shareware available, possible in the
> scientific world.

The NI driver page at http://www.ni.com/support/gpib/versions.htm
suggests that you have to pay them US $50.00 for a license to use the NI
488.2 drivers. Pretty lame, if that's true. My guess is that they are
expecting you (the end user) to cough up patent royalties that they (NI)
have to pay to someone else.

I would go ahead and download their "NI-488.2 (Win32) Version 2.2 for
Windows 2000/98/ME/XP" package (http://snipurl.com/9o9w) and see if it
installs. If they don't, you will not be able to use your controller
until you pay them $50.00.

Once you've successfully installed the NI 488.2 drivers, there are quite
a few shareware/freeware applications that will work with your hardware.
I've just released a new version of my HP 7470A plotter emulator that
works with any of the National Instruments interfaces
(http://www.speakeasy.net/~jmiles1/ke5fx/7470.htm).

3025. [Annc] New V1.6 version of GPIB utilities including HP 7470A plotter emulator available

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-10-10 22:22:40 UTC
From: John Miles <jmiles@pop.removethistomailme.net>
Message-ID: <MPG.1bd3560ce1db9632989736@news-central.giganews.com>
Source record: 22712
Cross-posted to: rec.radio.amateur.homebrew,sci.electronics.design,sci.electronics.equipment

```
See http://www.speakeasy.net/~jmiles1/ke5fx/7470.htm for download link
and release notes.

The current version of 7470.EXE has been able to capture screen dumps
from the following instruments using National Instruments GPIB hardware:

Advantest R3762AH VNA
Advantest R4131B DSO
HP 3040A cable tester
HP 8510B VNA
HP 8560A spectrum analyzer
HP 8566B spectrum analyzer
HP 8568B spectrum analyzer
HP 8591E spectrum analyzer
HP 8752C VNA
HP 8753A VNA
HP 8757A scalar network analyzer
LeCroy 9354AM DSO
Tektronix 2430A DSO
Tektronix 490P and 2750P series spectrum analyzers
Tektronix TDS694C DSO
Tektronix TDS784D DPO

Due to several improvements made in this release, many other instruments
should work fine as well... although 7470 is freeware and isn't
guaranteed (or even remotely likely) to work with everything out there.
Feedback is always welcome!

Sorry, but none of this makes sense to me. There's no diode involved
so I don't know where you get that from. And what's "input
capacitance" and "Q"?
Do try to speak in plain English!

The transistor acts like a tiny capacitor from base to emitter, in addition to its other jobs. Thus, an inductor in series with the base will act like a bandpass filter at

f = 1/(2*pi*sqrt(L*C))

An inductor and capacitor with the same values in parallel will act like a bandstop filter at that frequency.

Q is the "quality or merit factor" of the inductor, and is computed by dividing the 'reactance' (or AC resistance) of the inductor by the DC resistance *at the frequency in question*; it will generally be different at different frequencies. Q is really the ratio of reactive power in the inductance to the real power dissipated in the resistance, and can be computed by using the formula:

Q = 2*PI*f*L/ri

where f is frequency, and ri is the resistance of the coil at f. You buy inductors with a given Q range.

For an LC resonant circuit, the Q of the inductor will affect the 'Q' of the resulting resonance, which simply means that with a bigger Q, the passband or stopband will be wider. The Q of a resonant circuit is defined as the resonant frequency divided by the width of the passband.

Some more comments about solder paste:

Solder paste has a shelf life. Unlike wire solder it will go bad after a
time on the self.
It cost more than regular solder too. Its also hard to use on components
like IC's with close spaced leads. In the commercial world the solder paste
is put on the board before the components are by a silk screen like process,
then the components are placed. The gummy solder paste is used to hold the
parts in place or if the board is to be inverted, to mount parts on both
sides they are glued in place. The problem for the "home" user is putting
the paste only on the pads of fine pitch parts other wise its no better than
wire solder. The method I use is based on a solder tip for my iron made by
Pace. They call it the "mini wave" tip. It has a oval shaped pit that you
fill with solder. It's used by tacking down the IC by hand using 1 or 2
easier to reach leads, then painting the part liberality with liquid flux.
It looks and is messy, then taking this "mini wave tip" with the pool of
solder and letting the ball of solder just touch the leads on the IC,
quickly wipe the solder pool down the length of the row of IC leads.
Capillary action and the flux pulls the solder onto the leads and does a
very good job of soldering. It takes a bit of practice and some solder wick
to remove the solder bridges that can happen until you get the hang of it
but it works and I've done IC's with up to 164 leads this way. For small
parts like resistors and SOTS and the like I use a very fine tip iron and
lots of liquid flux. Cleaning up the flux can be a problem but there are
flux removers that work. Another way is to use water soluble flux. This is a
very active flux and CAN NOT BE LEFT ON THE BOARD. It must be washed off
with water SOON after use. It's used with solder that also has the same type
of flux in. Soap and water and a small brush works well to clean the water
soluble flux off and leaves you with a very nice looking board. All most all
electronic components are not effected by soap and water as this is the
standard commercial process.

Hole flow in semiconductor devices, which represents a positive charge
current, and certainly can be from 'plus to minus,' is arguably 'real.'

I would agree with you that anyone who seriously misunderstands any of this
and claims to be a practicing electrical engineer should be viewed with a
little skepticism. :-) If you're working with numerous such individuals, it
might be time to look for other jobs...

Hi Steve (swell name, by the way),
From this last comment, it appears that you have a lot to learn. Paul's was a pretty good explanation of a first step at understanding what might be going on in the circuit shown some time ago (an inductor in shunt with the base-emitter of the transistor).

The Base-Emitter in a transistor is a semiconductor junction just like a diode and in the (higher power) RF amplifiers behaves pretty much like a diode. With RF applied to the base, there will be conduction on the positive peaks only and this will constitute a DC current flow which must have a DC path. The inductor provides such a path since the capacitor can not. If this makes no sense to you then you, indeed are in over your head in an attempt to understand because it is pretty basic and simple. You will need to understand diodes and transistors first.

you say you are "really struggling here with with some of the terminology." Perhaps you can tell us which words are giving you heartburn?

I will respond to Paul's content, however, with this. The BE capacitance of this device, in this aparent application, I am pretty sure is not the dominant effect. The Rrverse biased capacitance is the wrong thing

to focus on. While it is interesting that that it and the inductor are near resonance, this probaly is not what is happening because this would make the inpedance looking into the base very high and difficult to get power to the base, contrary to Reg's hunch. The orignal ASCII cricuit simply had a coupling cap and a base-emitter shunt cap. It looks like class B or C. C more likely. Therefore the transistor is in conduction part of the time and not for another part of the time. Therefore we have a nonlinear, large signal condition. The base impedance under this condition (pulsed conduction) will be quite low and dominate and therefore, it will need some impedance matching to get enough into the base (from the preceeding collector). SO, I say that the inductor is :
1- Providing the obvious DC path and.
2- Impedance matching along with the "coupling" capacitor (did it have a value??)...BUT!

The one monkey wrench I will throw in, is that the Miller effect will also have a very significant effect on the input impedance of the stage. The Ccb is a path providing significant feedback and probably dominating the input impedance.

If you don't recall, the Miller Effect describes the capacitance looking into the base which looks like Ccb times the voltage gain (call it A). This is due to the fact that Ccb connects between the input / base and output / collector. Because the collector voltage is ~~ 180 degrees out of phase, with the base voltage, an input voltage change of, say one millivolt, on the input side of Ccb results in a change in voltage on the output side of Ccb of one milivolt times the voltage gain, A. This results in a total change across Ccb of A+1 milivolts and therefore a current change A+1 times a value that the 1 milivolt input change expected to see. This makes the capacitor look A+1 times as big as it actually is.

Finally, and possibly the most difficult to quantify (ok two monkey wrenches--nobody expects the Spanish inquisition), in RF circuits there is *very frequently* one other confounding factor and this is the circuit board layout and/or the actual physical construction. All the previous talk about how inductors and capacitors behave differently at high frequencies (I believe by Roy Lewallen) is nicely put, but the actual connection methods also can have a very significant effect on what value components are used. The "wiring" can add other capacitances and inductances which, very often, do not show up on the schematic. This can have profound effect on the components used, completely masking any hope of understanding of the circuit from the schematic diagram. As the power level in the circuit goes up, the impedances go down and short wires or PC board runs can become significant impedances, either to help or hurt the desired matching circuit.

Steve,
I'm not sure, but I think the original post said this stage was a frequency multiplier with an OUTPUT frequency of about 145 MHz. If that's the case, then the INPUT frequency would be 72 MHz or less. At that frequency, I don't think the choke and the input capacitance of the transistor are anywhere near resonance. Also, the coupling cap was stated as 1nF if I recall.

I think what we're looking at here is a DC -lock coupling cap and a DC-return RF choke....nothing more.

No Joe! The frequency is 145Mhz throughout.

An aside to Steve... I'm pouring over your expansive explanation.
It'll take a while to sink in, though!

Thanks,

Steve.

Okay, Steve, I'm gonna have to take your explanation in bite-size
chunks. Kindly indulge me...

I don't see that the inductor is necessary to provide such a path to
ground for the signal peaks, since they (the input signal pos. peaks)
turn on the transistor and complete the circuit to ground via the
base/emitter junction, which will be a low resistance path with
sufficient base drive level on the peaks. Can you tell me why this
path alone isn't good enough and there has to be an inductor across
B/E as well?

Thanks!

Steve

Steve,

If the inductor was not there to hold the zero-crossings of the input sine wave at zero volts, then the whole waveform would sink toward a lower DC voltage because it is capacitively coupled. You can prove this to yourself by taking a large capacitor and driving a diode that is connected to ground. The test can easily be done with audio frequencies if you don't have RF equipment. You could also simulate it on a program like SPICE.

If the choke were removed from the circuit, this input DC shift would reverse bias the BE junction, preventing the abiltiy of the waveform to drive current into the BE junction. No base current = no collector current = no gain.

BTW, I was almost sure your original post said this was a multiplier circuit. Did the word "multiplier" not appear in it anywhere? Hmmm...

OEM car radios are pretty much state-of-the-art design. They always have been. Today's models have ceramic IF filters, up conversion on AM, noise blankers, audio DSP.... The next generation will have digital IF. For some reason automakers have always been real picky about radio performance, and willing to pay for it! (Been in the OEM automotive radio design biz for 30 years.)

Hi!

In many European contries we have DAB (DIGITAL) transmissions, mostly along the main roads. I got my last car radio with DAB and also FM. You select a station and there it is, whithout any fallouts or noise on the whole trip, for instance from Oslo to Trondheim. Some entusiast complains about the compression, it is like MP3, but most people find the quality sufficiently good. If the DAB signal falls out, the FM takes over. It is also a very good FM-receiver. I very often listen to a station sending only classical music. Few FM stations relay that program, but with DAB you have it crystal clear all the time!

Is something similar coming stateside?

Alf

Well, the truth is I've never tested much beyond using the monitor to assemble simple code and test the unit (9600 7N1). I can dump the first 2K and haven't seen any errors.

I haven't touched this stuff in several years, and even then wasn't a guru. I'm re-training with the official Intel SDK-85 rev. C (hamfest bargain) with version 2.1 of the monitor (from my tech school days) . I'm using the SID/SOD and tapping off ahead of the current loop drivers (in fact they are still connect despite instructions to disconnect them) to the usual 1488/89 for rs232c. My biggest undertaking was getting the monitor in modern digital form by scanning the source code. I had plans to refine my skills and thought this would help. But as time went by I moved on to something else. Now I'm working on some other projects that require me to refresh my skills in this area. In all my schools years, my MCS-85 labs were always my favorite and decided to start back here. Next - re-learn the MCS-48 stuff and on to the modern 8051 derivatives.

Would the monitor source be of intrest to you? I'll have to look at the monitor again and see if I can understand your stack changes.

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday October 17th 2004
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20 for the first and
$15 for each additional at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,
will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and
W1XM/R-449.725/444.725 (PL 114.8/2A).

Sponsors: MIT Electronics Research Society
MIT UHF Repeater Association (W1XM)
MIT Radio Society (W1MX)
Harvard Wireless Club (W1AF)

The Heathkit HR-10B receiver (tube receiver) used an IF around 1681 kHz.
Other receivers of that era (1950's; 1960s) also used IF frequencies in this
range (above broadcast, below 160 meter allocation).

Sorry for the bandwidth, but...

Please note: my former ifwtech.com domain is NOT under my control any more.

I lost that domain name 3 years ago, due to my ISP's careless failure to renew it. Fortunately I also had the ifwtech.CO.UK name registered, and have been using that ever since.

What's new - and nasty - is that ifwtech.com has now fallen into the hands of a company that has reactivated it as a gateway to popup ads, premium-rate phone services and other dubious activities. The really nasty thing is that this new site uses keywords like "yagis" and "power amplifiers", so it can easily be mistaken for something of mine. It most definitely isn't.

Please check, in case you still have any old web links pointing to ifwtech.com. Now would be a *very* good time to update them to ifwtech.CO.UK !

Once again, sorry for the bandwidth... but be warned about other domain names that may have been reactivated as the "evil walking dead".

A former ISP I had used a few years back, apparently suffered the same
fate after they went under, the domain name was snapped up by a
spammer.

Steve,

It has been a couple of years since I have done a noise figure measurement so my brain may be a bit rusty, but I don't see anything wrong with this.

In fact, if you had a calibrated noise source, this is one of the 'official' methods of measuring noise figure.

An anecdotal story for you...

About four years ago (subsequently laid off :-( ) I was working for a company that was making a virtual (that is, used digital signal processing) RF/Microwave measurement system. One of our customers was a >>>Major<<< communications satellite builder. They were complaining that our system was not working right for measuring noise figure. I knew it was, of course, since I had written the software and thoroughly tested it :-). I used two different manual methods, one of which is exactly what you are doing (except for using acalibrated noise source) and got the same answer as my software. Turns out that they (the >>>Major<<< satellite builder) didn't know how to use their nosie figure meter!

You may be reduced to finding decent cans and building your own
transformers using toroids. Not the best solution, but a home made IF
can is certainly in the ham tradition...

Hello,
It has been almost a year that I cannot access QSL.NET.
It's not ISP problem, because I've tried at some friends house, and
they could not access as well.
It's not virus problem because I have formatted my PC.

I've heard that QSL.NET has blocked all access from South America. Is
that true?
Why?

This is very selfish of your part, Mr. Admin from QSL.NET (if for
coincidence you are reading this post):
My Radio-Amateur friends an I have always used QSL.NET as a way of
research, look for another ideas, and communicating with other
Radio-Amateur via internet.

You have just cut our access to the server.
Will this selfish and Infantile conduct be forever?

Thank you very much,
Hayato

> Thanks! Steve

Most certainly, Steve.... Indulge, I will.
This can get confusing... Steve Noskowicz here (K9DCI)

Joe Rocci tried, but I don't think he went through the proper step-by-step
explanation.

OK Here's what happens... Start with the capacitor completely discharged -
zero volts across it - right end same voltage as left side (whatever that
may be). On the first positive peak, some current flows through the base
emitter junction because the voltage on the right side of the cap is the
same as that on the left side. (this assumes there is at least 0.7 volts of
signal coming from the left. NPN transistors conduct current when the base
is about 0.7 volts positive.
The current is some quantity of electrons, right. Well these electrons
will start to "fill up" or charge the capacitor. Each time another positive
pulse happens, the right side of the capacitor collects more and more
electrons. This charges the cap more and more and makes the right side more
and more negative. There is no way to drain off this charge before the next
pulse comes along. The base-emitter junction will be reverse biased and not

conduct any current. I hope you see this because that's the key.
As the caps gets more charge from each pulse, the right side becomes more negative. After each pulse, it will take more and more voltage on the caps left side to get enough voltage on the right side (0.7 volts) to get to the base-emitter conduction voltage and get any current to flow.
The end result is that the capacitor will charge to the peak input voltage (less about 0.7 volts) and the base will never get to the 0.7 volt level. At this point, the base voltage will be swinging (with the input signal causing it) from about 0.7 volts plus to a value equal to *negative* the peak-to-peak input voltage (less the 0.7 volts). That's minus volts. The AC signal at the bacse will NOT be swinting equally around zero volts.

This could be viewed as what we call a "clamper circuit" The AC voltage AT THE BASE will have its positive peak "clamped" or moved to +0.7 volts and the waveform will extend from there as negative as the waveform is tall.

IF we had 5 volts peak (10 volts peak-to-peak) the cap left side, the base voltage will swing from +0.7 volts to -9.3 volts.

WHEW !
Did this work ???

Surely you've heard West Virginia Public Radio stations - call letters
generally WVxx. As of a few years ago they all had the AF function active.
I'll admit I haven't checked recently. WETA-FM/WETH-FM had AF some years
ago, but they turned off their RDS a couple of years ago.

> satellites.

Both sat system have had terrestrial repeater since Day One. They have a
continual fight to continue operating them. IIRC, the recent action merely
extended temporary operating permission. AM/FM broadcasters fear the
satcasters and are playing whatever game they can to restrict their
operation.

I had a 2.5-hour tour of XM this Monday. Billions of dollars invested.
They have around 800 terrestrial repeaters. My guess is that they have
60 to 75 percent of the number of subscribers needed to break even. One
meaningless statistic: they had 25,000 subscriber activations Christmas
Day 2003.

I have heard the Charleston outlet, but only once and before I had a RDS decoder. Reception to the east is pretty difficult from here - I've never heard South Carolina and have only one each N.C. and Virginia station in the log.

It was maybe 20 years ago that I read this article so I am a little
vague on the details but I seem to recall that it was a build up of
coke, drinks, cans that was a problem. So yes it would be metal to metal
contact.
Another problem it highlighted was the effect of guy ropes. Where a guy
rope is cleated and anchored there is often a short piece of the rope
left over that runs either beside the guy or just hangs there. Not a
problem if it is rope but if it is a wire guy then you can have a 1/4
wave aerial immediately attached to a corroded junction.

Thanks for the suggestions. I'll have a look at the web references.
Just a couple of notes on things that won't work.

> Noise performance of Mar's MMIC's should be noted on datasheets.

Yes, but they never show the range of noise figures, only a typical or
worst case numbers. Of course if the noise figure is very low (PHEMT)
then the variability is pretty small as long as the circuit is done
right.

> Terminate receiver with 50 Ohm resistor, measure output and label it
> zero dB.

This doesn't work, because the noise is dominated by the receiver
noise, not the resistor thermal noise (unless the receiver is very
very good !).

Ahhh...and therein lies the real problem for most hams. It just
occurred to me that there might be another solution to this (at least
at HF), which could be to generate noise at an accurately calibrated
level (as accurate as the power supply voltage) using a pseudo-random
digital signal.

Cans are made of aluminum now, but 30 years ago they were steel. Back then
it took some hand strength to crush a can, now a little girl can do it.

You might find Terry Ritter's work on getting a good noise source to
be of at least a bit (ahem!) of interest:

<http://www.ciphersbyritter.com/NEWS5/FMRNG.HTM>

There are lots of other hits in Google for a search on
'calibrated "pseudo random" noise'
(without the outer single quotes).

It's hard to generate good noise, and at least as hard to find it.

I've told this B4, but... It doesn't always have to be IM. There's what I dubbed the "screwdriver effect". Near (within 10 feet or so) a transmitting antenna (2 Meters works great) and receiver on a nearby frequency, rub a screwdriver, or other metal object onto another one.

The Apollo space program used ships at sea for communications. They had high power HF equipment (many kW) which interfered with the radar systems (multi-GHz). The deck railing chain sections used for removable sections were found to be causing the problem. The links move with wind and ship motion causing intermittent and noisy contacts which produced noise that modulated the HF RF field causing sidebands up into the GHz regions.

I observed similar on early car telephones @ 150 KHz. Noisy hood, bumper or trunk (or motorcycle seat spring) junctions caused noise that modulated the transmitter's radiated field which extended into the Rx band and desensitized the receiver. I developed a probe to sniff out the noise sources and bond (make solid) the connections.
One of the local repeaters has a similar problem when it gets windy. Everyone has scratchy noise on their signal, regardless of signal strength. Nobody wants to climb the tower and check every other installation and bolt for tightness or whatever...

The mean voltage on each side is the DC component. The fact that it's different on the two sides illustrates the fact that the capacitor is an open circuit to DC. The shape of the waveforms on the two sides of the capacitor are the same. That illustrates that the AC component is the same on both sides -- the capacitor is a short circuit to AC.

It's gonna

I use a 1N21 (in reverse breakdown) as an uncalibrated source up to
about 5 GHz. A friend uses a 1N23 to 10 GHz. But how can it be
calibrated without using professional test gear ? I don't know.

> What frequency are you using?

Anywhere from HF to 24 GHz is of interest ! I have used the relative
noise figure measurement scheme between 3.5 & 903 MHz so far.

> One thing to keep in mind is that any loss or
> mismatch can affect your measurement.

Indeed...I assume that the use of a reasonable minimum attenuation in
the step attenuator will minimize the effects of receiver input
mismatch on the measurement accuracy (assuming the attenuator is
itself well matched). I rather doubt that I would be able to homebrew
an accurate measurement system at 24 GHz (or even 10 GHz). But
construction tolerance issues should not be a problem at HF or (with
care) at VHF.

Thank you Henry for your reply.

I have though to this solution before and I made a simple simulation where coils remain the same: in this case the capacitance must be divided approximately by 12 (exactly square of 1.6/.455). So moving the frequency from 455 KHz to 1.6 MHz should probably imply to unwind some length of wire to keep a realistic capacitance including the stray one I can't avoid. Consequently I am now wondering if the optimal coupling between primary and secondary would still exist ? I hope it is but probably not and in this case the problem is not solved.

Does anyone have any experience in this domain ?

Some assorted comments and follow-on questions on your suggestions:

- (from bviel) The Elecraft noise generator is not a calibrated unit. They give a typical ENR but specifically state that it varies from unit to unit. Their low-level signal generator is calibrated (though perhaps not quite accurately enough) but this would bring in the issue of measurement errors between noise and sine-wave powers. And it only works at one frequency.

- (from bviel) Which MMIC did you find had flat noise figure to 1 GHz ? My experience is that MMIC NF specs are usually at a frequency above the flat part of the spectrum, as this is more indicative of the high frequency performance. Are there any with noise figure also specified, or at least well characterized, at low frequencies (within the spectral region where the NF is flat) ? But the other question with MMICs is the unit-to-unit variation in noise figure which I don't believe is ever specified. If all units of a given part have, say, between 2 and 3 dB noise figure then a MMIC amp could be a fairly good standard for amateur use, but if the variation is from 1 to 4 dB then the usefulness is limited, in my opinion.

- (from bviel) I don't have the JT-44 software but I did look at the (full) manual. On page 35 it describes the "Measure Sub-Mode" which allows noise levels to be compared. However it does not appear to support absolute noise figure measurements (unless you use a calibrated noise source). Is there more in the online help ?

- (from Mike Andrews) Terry Ritter's stuff seems mostly concerned with the degree of randomness rather than absolute output power, which makes sense as he is concerned with cryptography. But I did find, elsewhere on his web page,

http://www.ciphersbyritter.com/REALRAND/92102201.HTM

a low frequency noise generator based on a diode source followed by a limiting amp. I imagine this concept could be extended to HF by suitable choice of amplifier. I am not sure of the significance of the very different output waveform (pulses of random width and fixed amplitude) compared to the true random (Gaussian) noise from the diode itself. I am not sure if I am willing to tackle the math needed to understand this or to calculate the ENR - can anyone help ?

I think it depends on the recipient country as to what proxy and open
relay the spammers use. I have never received one from South America, or
relayed through there.

The sophistication of spamming systems are mind boggling. That's one of
the reasons they will never all be shut down. A good example was one week
last February, many Canadian ISP's got hit with spam relayed through
proxies on the US cia.gov and fbi.gov servers!!! Not only is that
sophisticated, that takes BALLS!

It's difficult to determine the real source of spam, since the From and Reply-To lines are always forged. (My email address appears on some, since spam bots pick it off the Web and use it in forged addresses. I see those often when they're sent to an invalid address and bounce.) SpamCop is a service which parses the message header to determine the true source of spam. It's not perfect, but does a decent job. I've seen .br as the source of quite a few spams I've run through their parser. Of course, the greatest number come from the US, or at least US ISPs, but then so do the majority of the legitimate messages to those of us in the US.

long post warning directed at Ratch...

Hi there Ratch. Comments inserted below, but I am using terminology that has been used for a long time and is commonly accepted. If the OP has problems, I prefer him to pose (sp) the questions for clarification.

Much of what you point out is right along the lines of the following examples.

ROM stands for "Read Only Memory", right?
RAM stands for "Random Access Memory", right?

Yet ROM is also "Random Access". Therefore, ROM IS RAM. These are conventions which came about by an imperfect system of terminology. Namely, whatever sticks gets used.

Example closer to this:

Does a "river flow"? Do you know what this means? I think you do, yet by your comment a river is a flow of watter and "a river flows" would be "incorrect". We could only say that "Water Flows".

While I appreciate youre desire to be correct, I do not believe the OP would be confused by my use of very common terminilogy and if he/she is, then the questions will come from them/he/she.

I would, however, ask that you comment on the concepts in question. Is it an explanation of *WHY* the coupling cap causes the Veb to go negative causing no conduction in the part?

"Ratch" <Watchit@Comcast.net> wrote in message

> > > >[...snippity snip...]
> > > > On the first positive peak, some current flows through the base
>
> Current does not flow. Current IS flow.

I agree (in a manner of speaking) that changing this to:

" some charge flows through the base emitter junction"
is "correct", but I maintain that it is _just as understandable_.

However, if I really wanted to use the word, current, how would you word it? What does current do when it does its thing? Since "flow" is included

in the term "current", would I say:
" On the first pulse, some current happens through base emitter junction." ?
We don't talk that way.

> > The current is some quantity of electrons, right.
> Er, no. Current is quantity of charge per unit time.

Certainly it is. However, the point is that the capacitor develops a potential difference across its two terminals because of the difference of charge between the two sides. I maintain that my use is common usage in the field. I agree that I could have said:
"The current is some quantity of electrons per time, right."
I believe that either way, the following sentence would provide the necessary train of thought.

> > Well, these electrons will start to "fill up" or charge the capacitor...

Then you say:
> A capacitor does not charge.

It is completely common to refer to "charging a capacitor". You will probably be very surprised that we also refer to "charging an incuctor". This use of the word "charge" no longer refers to electron charge (in both cases), though that is where the term originated. This "charge" is a generic term meaning, perhaps, to "impart come analog quantity", or "fill with some desired substance" which can be electrons, magnetic field, or Halon. Just like we may say to "charge a battery" or "charge" one of those glow-in-the-dark things by holding it near a strong light, then turning off the light to watch it glow brightly. Although we commonly "load" a spring, we could also use this convention (though unconventional for a spring) and charge it in some situation. We "charge" fire extinguishers, but no current flows there eigher and we "charge" gasoline at the pump. Still no electrons. It's common usage which may be imperfect, but accepted and understood as a result.

Going in to depth on a capacitor, you say...
> The net change of charge is zero for a
> capacitor going from zero volts to its breakdown voltage. That is because
> for each amount of charge stored on one plate, the same amount of charge
> leaves the opposite plate. Now it takes energy to accumulate or deplete
> like charges (electrons in this case) because they do not like to get
close
> together. This energy is stored in a electrostatic field proportional to
> the square of the voltage. Therefore a capacitor should be described as
> being "energized", not "charged". Ratch

While this is a detailed description of what may be some of the properties of electric charge and the capacitor, I did not believe that going down to this level of information helps understand how the Base bias goes negative in the target circuit. The operation of the capacitor is a lower level concept which I was hoping the OP had some understanding of. If

not, then more detail of capacitors would be evident from the OP's follow-up.

I'll do what I accuse you of doing and see how you respond.
I have to give the statement "net change of charge is zero for a capacitor going from zero volts to its breakdown voltage" some analysis.
First, I don't think capacitors "go" anywhere when we drive electrons onto one side. (do they sit in the back seat or front?)
Second, I could argue that there is a *change* of charge because there are more electrons on one of the capacitor foils than the other...but that's another thread. I'm just trying to reenforce my point that our use of terminology is imperfect, but in some circles it is accepted.
Oh yes, I don't believe electrons "like" or "dislike" anything... I don't think they can. They do, however, appear to have a repelling force when brought near each other.

Whether or not the net charge changes, we certainly have rearranged that charge such that there is one hell of a potential differennce between the capacitor plates. That is the point.

Gee, do modern capacitors have "plates" any more... so...what do I call these things, eh?

We "energize" circuits and light bulbs. Does that mean that there must be some stored charge differential, as in a capacitor, in order for us to use that term?

...Didn't see any more of your comments...

I maintain that it is common and acceptable for:
current to flow.
Capacitors to charge and discharge.

By the way, even though *you* also use some of this imperfect terminology, I know precisely what you **mean** when you say:
"for a capacitor going from zero volts to its breakdown voltage" - don't go anywhere
"charge stored on one plate" - no plates in many a common cap these days
"they do not like to get close together" - what other emotions do electrons have...

The point of the thread is:
If I replace all of my terms with yours, will the explanation then tell the OP why the inductor is needed ??

Okay, upon further thought about this there's still something amiss in
my understanding. I take what you say about the cap blocking out the
DC component of the waveform to leave the AC largely unaffected.
However, the term "clamping" AIUI means the diode lops off anything
over about 0.7 volts from the input waveform (ie, it conducts it away
to ground) so around half of it is lost (half wave rectification). Now
you state (and the spice progs agree) that what *actually* happens in
this case is that the whole AC waveform gets shifted south into
negative territory. It's still a full wave, but it's way down into
the negative and only the highest peaks just creep above zero volts.
Is this effect *solely* attributable to the steady build-up of
negative charge on the cap's RHS? I think what's really freaking me
out here is the fact that the signal source is grounded on the neg.
side and yet we have that same signal that after going through a cap
can end up going fully negative *below* ground. It just seems like any
such voltage beneath zero/ground potential is breaking the laws of
physics. Ground should be the 'absolute zero' of the potentials in any
circuit and here it is being violated. I need some help to get my
thick head around the concept! :-(

Can you measure the noise power of the noise source by comparing
the output (through the RX) with the power from a signal
generator (again through the RX) of known output power?
Presumably using some form of averaging of multiple readings
across the RX passband.

Thanks for re-posting that Steve. I don't know where I got the crazy idea
that this was a multiplier stage....maybe I'm confusing this with a
different thread.

Thanks
Joe

Can only find this from RSGB TVI book

13. The rusty-bolt effect

High-pass filters (at the television receiver aerial terminals) and low-pass filters (at the transmitter) do not always cure TVI problems. Substitution of other TV sets can generally show if the cause is a faulty transmitter or faulty television receiver, but if substitution shows the interference effect to continue, then the cause becomes more difficult to establish. The ''rusty-bolt" effect is one of the hardest of all these TVI causes to locate.
If a known clean transmitter is causing interference to a known good television receiver, then an external cause can be suspected. Perhaps the transmitter signal is being picked up by a local conductor such as a clothes-line or fence-wire. A rusty or corroded joint in this conductor may be acting as a diode. Harmonics of the transmitter signal could be produced by this spurious diode detector and re-radiated. These harmonics can be received by the television receiver and cause interference to the picture or sound.
Such interference may vary with the weather. It may be intermittent and be affected by wind as well as rain.
Typical offenders are metal-tile roofs, metal gutters and down pipes. A heavy blow with a hammer may sometimes correct an offending joint. Applying water from a hose can sometimes change or remove the interfering source and help to identify the culprit.
Either bonding or insulating the offending joint may solve the problem. More than one joint may be causing trouble. Bonding is generally impossible with metal tiles. Shifting the television aerial away from the offending harmonic source or sources is a more practical cure. A bonded wire mesh over the offending joint may be considered. It is unlikely that a complete metal roof will have to be bonded to effect a cure.
Bonding suspect joints can sometimes produce problems. With bonded conductors, a better signal pick-up may result, larger radio frequency currents may flow, and the problem may shift to another joint that was hitherto not suspect. Insulating the suspect joints may sometimes be more effective. A change to nylon guy-wires may sometimes eliminate problem joints.
The accepted rule is that if the offending joints are on the amateur's property, the problem is his. If the offending joints are on the property of the television set's owner the problem is his, Unfortunately, few set-owners understand this problem and so the radio amateur should offer technical assistance and advice. Re-siting the television set aerial or the transmitting aerial is often the only practicable cure.

3106. Re: Noise Figure Measurements

You also have to know the noise bandwidth of the system to use this method. If the response is dominated by a single, fairly steep-sided filter, this is easy. But otherwise (such as if both IF filtering and AF amplifier response shape the overall response), some calculation and/or measurement is required. I've gotten what I believe are reasonable results on HF and AF amplifiers using this method. But I haven't tried it on a really low NF system, so would heed Jim's caution.

|
|> ....any errors
|> in the measurement can easily outnumber the actual noise figure
|
|Thanks for reminding me of that one, Jim. But I see your point about
|errors. For example, in measuring the gain one needs a standard. One
|of the few pieces of real test gear I have is a bolometer-type RF
|power meter which can measure about -13 dBm accurately. If the
|measurement bandwidth is 1 MHz (suitable for VHF, perhaps) then
|thermal noise is -114 dBm. So I need about 100 dB gain for a very low
|noise figure DUT. To measure that I might need five 20 dB attenuators
|as a standard, each with perhaps +/-0.5 dB accuracy if I am lucky...so
|there's +/-2.5 dB error (well, I suppose I could cross my fingers and
|RSS the numbers). Or I have a diode-type power meter that will
|measure lower power, which leads to issues of how the detector
|responds to noise. And then there's the problem of knowing the noise
|bandwidth precisely...
|
|> is where half my gray hairs came from (the other half from being laid off).
|
|I think about half of mine come from the latter factor too !
|
|> If you are measuring an entire receiver there are a few things you have to
|> be careful with. The receiver must be a linear receiver (no FM, AM diode
|> detector, etc.---basically just SSB). There should be a filter to pick just

|> linear region, which also applies to a simple amplifier.

|
|Definitely. Though, with my method the input never gets more than 3
|dB above the receiver noise floor and in most cases a well designed
|receiver will have no AGC response at that level. But with a preamp
|in front it usually will activate the AGC, so AGC has to be switched
|off when comparing preamps - which of course is impossible to do in
|most ham rigs !
|>
|> If you have a DUT with a known noise figure, I think that this would be one
|> way of calibrating a homebrew noise source.
|
|Hence the interest in NF repeatability of MMIC amps, since they are
|hard to build wrong, are well matched over a wide bandwidth and don't
|require tuning for best noise figure. The known DUT can also be the
|standard itself (in association with a receiver of only roughly known
|NF) to avoid issues of errors in calibrating the noise source ENR.

Re rusty connections!
Apparently there was a situation in UK many years ago where an electric
heater with the old fashioned heating 'coils' was picking up radio waves.
Also a poor connection became a rectifying junction (something like an old
time crystal detector) and the metal of the heater became a sound box.
When some interference problems were being investigated the elderly lady who
owned the heater was asked why she hadn't mentioned or complained about it.
Her reply was that she enjoyed hearing the voices and the music that came
from the heater!
Cheers. Terry.

> I am hoping that accuracies of +/- 1 to 2 dB might be achievable.
If you are satisfied with +/- 1 to 2 dB variation, the link I gave to
the Mar MMIC 35dB "calibrated" Noise generator should be
accurate enough.
That why I "forgot" the approximatly statement.

You can not compare noise power with a calibrated sine wave generator.
That's right, not directly.
You can calculate the RMS for a sine wave.
Also calculate the RMS for noise power, but its another formule.
Use the same impedances and frequency's.

If you know the amount of (milli) Ampere's through the noise diode and
know the impedance of the load, you can make power calculations like
we do with DC.
With the calculation method you don't need to have a calibrated noise head.
Someone else discussed the method, let me give the formule.
The formule is in Chris Bowick's book RF Circuit Design.
Its about Shot Noise. (Not thermal)
In^2 = 2qIdcB

In^2 = the mean square noise current
q = the electron charge (1.6 x 10e-19 coulombs)
Idc = the direct current in Ampere's
B = the bandwith in Hertz

Onces you have the mean square current, calculate the power in the load
resistor.
Did not made calculations with it, since I have the opportunity to measure
noise
right away. Will do it in future to check the formule.

The MMIC I used.... I was afraid there would come a question about it.
It's in a factory designed preamp of Japanese origin, has a forgotten
product
number, I mean National, not sure of that.
Searched hours for datasheets, because I was convinced the NF of the device
was less at 144Mhz, the manual stated approximatly 2dB 2Ghz.
EME use 144Mhz, with the knowledge of bipolar transistors that have an
increase of NF with frequency, 144Mhz would have a NF of about 1 - 1.5dB.
The manual said nothing about a lower NF at lower frequency's.
So bought it with the deal, not good money back.
Found the datasheets, the NF was 2.8dB flat from almost DC to 2Ghz.
From there comes the idea of flat NF respons of MMIC's.
I brought the device back to store and got money back. 150$.
More research learnt me that similar devices with less NF in order of 0.7dB

were avaiable for 20$, OK no box around it, no blinky leds.
I know only that the MMIC is obsolete today, forgot the type number.

A single mosfet, BF981 does 1.7dB at 100Mhz and cost about 1$.
I love homebrewing.
With that device you could also calibrate your noise generator.
It matched the input impedance of the 50 Ohm receiver.
Many EME amateurs use it in their preamps.
If they all use the same scheme it would be accurate within a variation
of say +/- 0.1dB ?

Since I can measure noise power, how to calibrate whitout a calibrated
noise head is not a hot item for me anymore.
Just practice.
Before that, I read several books, spent hours on the internet, collected
many
data.
Its only to share thoughts, nothing science, professional or years of
experience,
and yes I can be wrong.
The goal was maybe you can do something with it, for me, maybe there is a
clever
way to determine the NF without calibrated noise head, maybe even whitout
math.

The JT44 software program, I just finished the interface from receiver to
PC.
Details at the original PSK31 homepage.
Used a "Jensen" audio trafo, to prevent ground loops.
A lot to do... no practical data at this moment.

Have read Terry Ritter's stuff.
He said, no white noise at all. Just pink. See the graph's.
Read in some university books, noise is of pink behavior at the lowest
frequency's.
The graph showed the audio band.
White noise is flat (whitin 15 - 20Khz partitions) and at higher
frequency's, and random.
Whit respect to the measurements of course.

There is an increase of NF to higher frequency regions.
How came that MMIC to a flat respons ?

Sorry I was wrong about the noise figure at 100Mhz for the mosfet BF981.
It has to be 0.7dB instead of 1.7dB!

It can still better with the BF998, to get an impress of the scheme try the
following link http://lea.hamradio.si/~s53ww/4xbf998/4xbf998.htm

I think it can be reproducible whitin small variations.

In connection with the QST article by Bill Sabin, W0IYH, NoiseCom had a program of single-quantity sales to amateurs, and offered a low-cost calibration service. I'm not sure whether that program still operates, but some years ago NoiseCom were very helpful in supplying a free sample outside of the USA.

If I were building a noise source again, I wouldn't put NoiseCom to any trouble. Instead, I would use the base-emitter junction of a small-signal UHF/microwave transistor. It seems that just about any junction that goes into avalanche breakdown at a reverse voltage of 5-7V will give an Excess Noise Ratio of about 35dB. With a modern SMD package, the device parasitics will be lower than the wire-ended diodes that NC were offering, so the ENR will be flatter with frequency into the microwave region.

ENR flatness of the whole noise source depends on your construction. The other important factor is that the output impedance must not change significantly between the 'on' and 'off' states of the diode. To achieve both of these, the best technique is to build the noise source using SMD/microstrip technique including an attenuator of about 7dB made from 0805 SMD resistors; and then buy a high-class 20dB attenuator (N or SMA) which need not be expensive at a hamfest. This attenuator then becomes a permanent part of the noise source - not to be taken off and used for something else!

This level of attenuation will give you an ENR of about 5-6dB, which is what you need to measure typical modern low-noise amplifiers.

On the DC side, it is a very good idea to include a constant current source for long-term stability of ENR. Most devices will give a peak of ENR at a few mA, so you need to adjust the current to the top of this peak where the variability is least. (There is much more noise at currents of a few hundred uA, but you don't want to go there - the noise output there is far too sensitive to the DC current, temperature, color

of carpet, phase of moon etc.)

It is VERY important to design for the industry-standard power supply of +28V DC, so that your noise source is a simple plug-in replacement for any professional source... because that is how you're going to get your ENR calibration.

All of these ideas come from an article by DJ9BV in DUBUS magazine which described a very high-class noise source, good up to 10GHz. Mine uses simpler and much less precise construction, so the ENR begins to wobble above a few GHz due to resonances.

The DJ9BV articles (in both English and German) are on the DUBUS website, at:
http://www.marsport.demon.co.uk/archive.htm
Look around 1990, and there are a few follow-ups in later years.
(Unfortunately both archive sites are down right now, but do keep trying - these articles are *exactly* what you've been looking for!)

As for calibration, the best way is to take your noise head to a microwave meet where there is professional NF measuring equipment, and take a cal from the HP346A there. Alternatively, get to know someone - anywhere - who has access to these facilities, and can do it for you one lunchtime.

Other useful background information is in an Agilent App Note, at:
http://literature.agilent.com/litweb/pdf/5952-3706E.pdf

If you can still find a copy of 'The VHF/UHF/DX Book' (out of print) there's a lot of information in there too.

Absolutely! Both hard cover and soft. It ought to be in your library. Look at page 216 in the soft cover, my personal favorite. If you're too young for it, there was an earlier one that was an all time classic, "Solid State Design for the Radio Amateur" by DeMaw and Hayward. Called SSD by those who slept with it, the latest is often referred to as SSSD, "Son of Solid State Design".

From: chafik.philo@eudoramail.com
Message-ID: <cacbc942.0410150755.49768f5b@posting.google.com>
Source record: 22548

Hello
I have an IC-706 MKII, works fine on all modes except SSB:
On receive,I look at the audio spectrum analyser software, I have
found the following:
in LSB mode, most of the BF energy is located
between 1200 Hz and 2800 Hz approximativly.
in USB mode, most of the BF energy is located
between 200Hz and 1800 Hz approximatively
Fortunatly I can fix the problem by turning the IF shift knob about
-500 Hz in order
to have a normal audio quality.
(NB: the IF shift knob shifts the first oscillator and the BFO by
+-1200 Hz)
But the problem is getting worst while Transmitting since the other
station receive only the lower frequencies of my voice in USB mode,On
LSB mode
the other station receive only the Higher Frequencies of my voice
which give
a hard to copy modulation. the IF shift is not available on Transmit.
On other hand,the output power is only about 30 % on LSB and 70 % on
USB.

So, I dont know if the SSB filter is broken or that the some
oscillator is
off frequency by 500 Hz.
In the Service Manua, I did not found any way to play whith the
oscillator
or the BFO frequency.
Any Idea please.

That's correct; it is only a design guide to the amount of attenuation
that will be needed to give an ENR that's in the right ballpark. But
then you need to know what the actual value *is* - and for that, you
still need a calibration.

You can optimize NF using an uncalibrated source, but with this kind of source you cannot can make worthwhile quantitative measurements without an external calibration.

I've had a copy since it was first published in 1982. It's intended to be more of an engineering textbook than the more cookbook-like _Experimental Methods. . _ and its predecessor _Solid State Design for the Radio Amateur_. (Although those books are much more than cookbooks.) Now published in a second edition by the ARRL, it's an excellent reference. It also contains insights into the fundamental workings of circuits that you'll find in few other texts. As just one of many examples, the discussion of oscillators presents some unique insights into the similarities between oscillator types and an understanding of the fundamentals requirements of oscillators.

I highly recommend it for anyone interested in understanding electronic circuits on a more basic level. It nicely complements his other books, and it's a bargain at the price.

DAMN! And I sort of thought of this as I was writing it... STUPID ME! I
did what I (in my mind, usually) will normally criticize others for doing
soften here in an attempt to "help" others "fully understand". Namely,
adding some additional explanation or extreme detail which only serves to
further confuse the OP. Please excuse me.

While not necessary for understanding this circuit, I'll fill-in this bit
here. A "clamper" is a diode and cap circuit which will clamp a particular
point on a waveform to a specific voltage (kinda like being clamped in a
vice on the bench), but NOT change the wave's wiggling *shape*. Sometimes
this is needed. In the coupling circuit in question, it is the POSITIVE
PEAK of the signal that gets clamped to +0.7 volts. The wave's SHAPE is
un-changed, but the whole thing is shifted in its DC component.

What you are thinking of is called a "CLIPPER" because it CLIPS *off*
part of the waveform like barber's scissors.

Back to the actual subject.

In general, any waveform can have an AC component and a DC component.
The DC component only serves to "shift" the position of the signal up or
down; which can also be called a DC offset.

> Now

Continues a wiser Steve Evans:
> you state (and the spice progs agree) that what *actually* happens in
> this case is that the whole AC waveform gets shifted south into
> negative territory. It's still a full wave, but it's way down into

> thick head around the concept! :-(

Oooooo. BEWARE! GROUND IS NOT ABSOLUTE ! ! ! Nope, nope, nope. This is going to take some time to explain and more experience/study will be needed for you to really _get it_.

The bad news for you may be that ground, I must sadly inform you, is relative. There is no one, solid, never varying, absolute thing which is ground, except in our imaginations. Many hams believe there is, but there isn't.

That being said, let's start out simply and build.

Here is a very applicable analogy:

Voltage, also called "potential difference", is a lot like altitude -- height. We can talk about the height above the street level. We might consider the street level to be "ground". In Physics, moving some object to a higher level gives it the "Potential" to do damage if it falls on your head, so the "potential energy" of it is greater. Holding it three feet above your head gives it a certain potential, right? Voltage is just like this.

HOWEVER, what about standing on the roof of a building THEN moving the same object three feet above your head. You must agree that it has the SAME potential to do damage TO YOUR HEAD that it did in the first example, right? In this case, the roof of the building is our ground. So ground is relative and *we* get to pick it. It is usually a known point in our circuit and we use special symbols to show it. Note that this is why voltage is also is called potential *DIFFERENCE*.

Unfortunately, this analogy will fall apart when trying to use it for negative voltage, if we put this negative voltage "Below" our ground, but for the "relative" concept, I hope it worked.

Now I'll try *negative*.

Ground is a REFERNCE to which we relate all the other voltages in the circuit we happen to be talking about.

Lets put a screw into a wooden board and call it our ground. Work with me here, Steve. Connect a wire and run it over to several other screws in the board. They are all now our "ground".

Take your basic Ray-O-Vac flashlight battery. [[actually, for Ratch, this is a "cell", but common usage dies hard. A "battery" is a collection of cells usually connected in series to get a greater voltage]]]. Run a wire from the negative terminal of the battery...oops, cell, and connect it to our ground.

Now, with the negative lead (rhymes with seed) of our volt meter connected to our ground, measure the voltage on the Ray-O-Vac positive terminal with the positive lead of the voltmeter. We get + 1.5 volts.

In electronics (when we want to study some phenomenon carefully) we have a convention of ALWAYS putting the NEGATIVE lead of the voltmeter on our ground. That way we can easily see if the voltage it is positive or negative.

NOW... reverse the connection on the Ray-O-Vac. You will now measure a NEGATIVE 1.5 volts. So what's the way to interpret this.?

Voltage (potential difference) is also called Electro Motive Force because it is the "force" that "pushes" the electrons around the circuit to form Ratch's (and everyone's) current flow (sorry, Ratch, couldn't resist pulling your chain a bit in some friendly ribbing (:-).

When we reverse the battery/cell, we are now "pushing" in the other direction. It is still a potential difference, but negative.

In MY model (the one in my head), I visualize this as being "physically" below ground (and we often refer to it as being "below ground") in the sense that on the oscilloscope and Pspice display it is below on the graph.

If you REALLY want to make the altitude analogy work, you can imagine that gravity always "pulls" things toward the "ground" - but this is YOUR local ground. Then the negative potentials "pull you up".

END.hope this helps, Steve.

It's great; definitely get a hold of a copy if you're interested in radio
design.

"Introduction to Radio Frequency Design" is somewhat unique in that the
level it's written at is sort of inbetween the "cookbook" approach and the
"highly theoretical, filled with math" approach. It's aimed at individuals
who have something of a formal background in engineering but who (1) don't
want to get bogged down in the math just to get some results and (2)
appreciate having the references to the hard core material so they can
investigate further if need be. This is unlike, say, Joe Carr who seems to
want to target a similar audience, but usually his 'reference' list is
non-existant or pretty generic; Wes will direct you right back to Zverev,
Matthei, Rhea, etc. if you're so inclined. (And whereas someone who only
reads Zverev is probably a LONG way from actually being able to build
anything outside of a SPICE simulator.)

Check out Wes's web page here: http://users.easystreet.com/w7zoi/books.html
... for information on all of his books. His books are also still quite
reasonably priced. (It's not out of line, but I'm still surprised that in
ten years the ARRL handbook has gone from $25 to $55... essentially from 'a
real bargin' to 'about the usual price' for such books.)

3121. Top coupled resonators (more bandstop filters)

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-10-16 00:47:58 UTC
From: Joel Kolstad <JKolstad71HatesSpam@Yahoo.Com>
Message-ID: <iZqdnZfWCfMb8u3cRVn-jQ@comcast.com>
Source record: 22551

I've been reading Wes Hayward's articles on coupled resonator filters, and I've simulated some of the results and they're what I'd expect. However, his examples are all bandpass filters... and I need a bandstop filter. Chanigng the parallel LC shunt resonators to series LC series resonators doesn't really work at all... although there's a perfect notch at the desired center frequency, the passband response is very low (tens of dB insertion loss) and recovers very, very slowly. It seemed as though I just needed a different size coupling capacitor, but playing around some doesn't improve the response significantly (for instance, if you take the example on page 85 of Introduction to Radio Frequency Design and change the parallel resonators to series resonators, even if you change the 7.2pF top coupling capacitor to something astronomical such as 1nF the response is still poor).

I've ordered a copy of Zverev's book (and Zverev w/Mathei), where the theory of all this comes from, but in the interim... can anyone suggest what the fundamental problem might be? Interesting, from looking at a few pages of Zverev on Amazon.Com he does have schematics of what I think I'm after (top capacitor coupled series resonators to create bandstop filters).

Thanks,
---Joel Kolstad

Then you agree that the French did learn something from their disaster in
Indochina. But not enough to avoid invading Egypt in 1956. Maybe the
post-grad course in Algeria was what turned them into peace-loving
post-colonialists.

Yes, the French have tried mightily to avoid foreign provocation. Why, take
Rwanda. As the genocide reached its peak in the early summer of 1994,
France's President Franï¿½ois Mitterand was reported to say, "In such
countries as this, genocide is not too important." IIRC, the French Foreign
Legion was really on a protracted African vacation in Zaire in 1978.

I cite these instances not to demean France (although I think the average
Frenchman deserves a better government than he usually gets), but to deflate
the Francophile pomposity you wear as a veneer over your hatred of America
in general and the present administration in particular.

Nothing I say will change your pickled attitude, so I'll grant you the
high-ground of a last idiotic reply.

"A river flows" is a rather poetic description. If the Army Corps of
Engineers installed a flow meter in a river, would they label it "river
flow", "water flow", or "rate of flow?"

"Charge" is used in electronics as either a noun or a verb. I shun
using it as a verb in electronics because it can be
confusing. It is surprising how many nubes think that charging a battery or
a cap means filling it up with electrical charges
so they can be removed and used later. The word "energize" is more
descriptive. There is no problem in using "charge" with respect
to filling a gas tank or using a credit card. This is because we are not
adding/removing "charges" on these items. Furthermore, unlike a cap, we are
actually increaing/decreasing their net quantity of gas or credit.

Your hope is probably justified. I was explaining why I thought a cap
should be thought of as energized.

Indeed, the charge is imbalanced.

>
> Gee, do modern capacitors have "plates" any more... so...what do I call
> these things, eh?

I believe they do, whether they are folded, interleaved, rolled, or
bifuracted, they can still be analyzed as a sandwitch
with a dielectric filling.

>
>
>

> We "energize" circuits and light bulbs. Does that mean that there must be
> some stored charge differential, as in a capacitor, in order for us to use
> that term?

No, the word energize means to imbue energy to something. We can create
a electrostaic field in a capacitor, or
a electromagnetic field in a coil, or dissipate heat and maybe light by
creating a current through a resistor. Either way the
circuit is energized.

>
>
> ...Didn't see any more of your comments...
>
> I maintain that it is common and acceptable for:
> current to flow.
> Capacitors to charge and discharge.

Yes, and many folks think that R=V/I is Ohm's law, which it is not.
Ohm's law refers to the resistive linearity of a
material, not the resistance formula. But everyone first thinks of that
formula when you say "Ohm's law".

>
> By the way, even though *you* also use some of this imperfect terminology,
I

I should have been more descriptive and said "its voltage value goes
from ..."

> "charge stored on one plate" - no plates in many a common cap these

No plates or their equivalent? What then?

> days
> "they do not like to get close together" - what other emotions do
> electrons have...

Yes, I should have said they repel each other. I was giving the
electrons anthropic properties they did not deserve.

>
> The point of the thread is:
> If I replace all of my terms with yours, will the explanation then tell
the
> OP why the inductor is needed ??

Only the OP can answer that one.

One of worse descriptive phrases comes from NASA when they refer to
their astronauts as "space walking." Everyone
knows what they mean, and all can see that they are floating or drifting,
not walking. I always wanted to ask NASA what would
happen if their tethers separated. Would the astros walk away, or float
away from their ship? I liked it better when they
referred to that activity as EVA. Walking in space to me means walking on a
structure in space wearing sticky boots. Ratch

3125. Large capacitor question

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-10-16 08:58:51 UTC
From: Prune <bobysgotguns@yahoo.com>
Message-ID: <Xns95841426C36E8Gormenghast@64.59.144.76>
Source record: 22559

I got several used tin can capacitors, 40 uF @ 3 kV, about 8 pounds each, probably film in oil. With such capacitors, is there any potential problem if I do not keep them upright during operation?? Normally I would assume that wouldn't be an issue, but I've never used such heavy caps before, and especially as they are old with a few small dents on the casings, I'm worried whether stuff may shift inside if I work them horiziontally.

Because it agreed exactly with Steve's prediction. I think therefore
I'm entitled to rely on it in this instance at least.

Oh, blast! You were doing so well there for a while, Roy. Now you've
gone and spoilt it all by using that word "basic." I was hoping for
something at least "intermediate" and I don't really see how "basic"
and "RF design" sit easily together in a single description. Please
tell me it's useful for more advanced stuff too!

Maybe is it that someone's basic level is someone else' intermediate level ?
;-)

You guys must be reading a different IRFD than me, or maybe I'm just dumber
than I thought. That book has more math in it than my college EE text. OK,
admittedly the math isn't as weird, but I wouldn't call it "basic".

It seems to me that the unit simply needs alignment. Get a service manual and go through the alignment step by step. You will need a frequency counter, oscilloscope, and some other gear as listed in the manual. Otherwise, find a friend with this stuff and that should fix it. I don't think the filter is the problem. The oscillators have to be set.

Okay, Steve, I've snipped your explanation about negative voltages as
that wasn't quite what I was getting at. I'm familiar with the
analogos you used (which I'm sure will help ohters in future via
Google). I've done quite a lot of experimentng with opamps using split
supplies, hence I don't have a problem envisaging below ground
voltages where the supply is say +15V - 0 -15V. The problem I was
having was with below ground voltages in a circuit with only one
ground and one V+ supply! I'm gojng to have a good think about this
before posting back for further clarification. I'm not completly sure

that its all down to the cap alone. Mebe the diode has an effect on t
producing his sub-ground signal as well?

Steve

Paul, maybe you should stay away from it because apparently you can't
read.

At the beginning, Roy said, "It's intended to be more of an engineering
textbook than the more cookbook-like _Experimental Methods. . _"

At the end he said, "I highly recommend it for anyone interested in
understanding electronic circuits on a more basic level." This is
apparently where you got confused. Oh, and he never specifically
mentioned "RF design".

English can be tricky. In the context of the rest of the message, I take
Roy's, "understanding electronic circuits on a more basic level," to
mean at the level of the basic principles that define the circuit's
functions, not less than advanced. As Roy and others have said it is
MORE rigorous and mathematical than the other books.

If you were trying to make a joke, you should have ended with a happy
face.
